RATIONAL POINTS ON GENERALIZED FLAG VARIETIES AND UNIPOTENT CONJUGACY IN FINITE GROUPS OF LIE TYPE

SIMON M. GOODWIN AND GERHARD RÖHRLE

ABSTRACT. Let G be a connected reductive algebraic group defined over the finite field $\mathbb{F}_q$, where q is a power of a good prime for G. We write F for the Frobenius morphism of G corresponding to the $\mathbb{F}_q$-structure, so that G^F is a finite group of Lie Type. Let P be an F-stable parabolic subgroup of G and U the unipotent radical of P. In this paper, we prove that the number of U^F-conjugacy classes in G^F is given by a polynomial in q, under the assumption that the centre of G is connected. This answers a question of J. Alperin in [1].

In order to prove the result mentioned above, we consider, for unipotent $u \in G^F$, the variety $\mathcal{P}_u^0$ of G-conjugates of P whose unipotent radical contains u. We prove that the number of $\mathbb{F}_q$-rational points of $\mathcal{P}_u^0$ is given by a polynomial in q with integer coefficients. Moreover, in case G is split over $\mathbb{F}_q$ and u is split (in the sense of [20, §5]), the coefficients of this polynomial are given by the Betti numbers of $\mathcal{P}_u^0$. We also prove the analogous results for the variety $\mathcal{P}_u$ consisting of conjugates of P that contain u.

1. INTRODUCTION

Let $\mathrm{GL}_n(q)$ be the general linear group of nonsingular $n \times n$ matrices over the finite field $\mathbb{F}_q$ and let $\mathrm{U}_n(q)$ be the subgroup of $\mathrm{GL}_n(q)$ consisting of upper unitriangular matrices. A longstanding conjecture states that the number of conjugacy classes of $\mathrm{U}_n(q)$ for fixed n as a function of q is an integral polynomial in q. This conjecture has been attributed to G. Higman, and it has been verified for $n \le 13$, see [31]. There has also been interest in this conjecture from G. Robinson (see [18]) and J. Thompson (see [30]).

In [1] J. Alperin showed that a related question is easily answered, namely that the number of $\mathrm{U}_n(q)$-conjugacy classes in $\mathrm{GL}_n(q)$, for fixed n as a function of q is a polynomial in q with integer coefficients. Generalizing this result, in Theorem 4.5, we give an affirmative answer to a question raised by Alperin in [1]. In order to state this generalization we need to introduce some notation.

Let G be a connected reductive linear algebraic group over $\mathbb{F}_q$, where q is a power of a good prime for G. We write F for the Frobenius morphism corresponding to the $\mathbb{F}_q$-structure on G; then the F-fixed point subgroup G^F of G is a finite group of Lie type. Assume that the centre of G is connected. Let P be an F-stable parabolic subgroup of G with unipotent radical U.

In Theorem 4.5 of this paper, we prove that the number of U^F-conjugacy classes in G^F is given by a polynomial with integer coefficients (in case G has a simple component of type E_8, we require two polynomials depending on the congruence of q modulo 3). This generalizes the aforementioned result of Alperin, firstly by replacing $\mathrm{GL}_n(q)$ by an arbitrary finite reductive group G^F and secondly by allowing any parabolic subgroup of G^F rather than just a Borel subgroup.

In order to prove Theorem 4.5, we are led to consider the $\mathbb{F}_q$-rational points in certain subvarieties of the variety $\mathcal{P}$ of G-conjugates of P. Given $u \in G$ unipotent, we write $\mathcal{P}_u$ for the subvariety of $\mathcal{P}$ consisting of conjugates of P that contain u and $\mathcal{P}_u^0$ is the subvariety of $\mathcal{P}_u$ consisting of conjugates of P whose unipotent radical contains u. We prove that the number of $\mathbb{F}_q$-rational points of the variety $\mathcal{P}_u$ (respectively $\mathcal{P}_u^0$) is given by a polynomial in q. For a precise formulation, see Theorem 3.10. Assuming that G is split and that $u \in G^F$ is split (in the sense of [20, §5]) we show in Proposition 3.15 that the coefficients of the polynomials describing the number of $\mathbb{F}_q$-rational points in $\mathcal{P}_u$ and $\mathcal{P}_u^0$ from Theorem 3.10 are given by the Betti numbers of the underlying varieties.

We now give an outline of the proofs of our principal results and the structure of the paper.

In order to state our main results precisely, we require an axiomatic formalism for connected reductive algebraic groups; this axiomatic setup is given in §2.2. Further, to make sense of considering the varieties $\mathcal{P}_u$ for different values of q, we need a parameterization of the unipotent G^F-conjugacy classes that is independent of q; the relevant results from [20] and [12] are recalled in §2.3.

For our proof of Theorem 3.10, we require results from the representation theory of finite groups of Lie type to express $|\mathcal{P}_u^F|$ and $|(\mathcal{P}_u^0)^F|$ in terms of Deligne–Lusztig generalized characters. Consequently, $|\mathcal{P}_u^F|$ and $|(\mathcal{P}_u^0)^F|$ are given as linear combinations of Green functions. Due to work of T. Shoji ([20]) these Green functions are given by polynomials in q; from this we can deduce Theorem 3.10. The relevant results on Deligne–Lusztig generalized characters and Green functions are recalled in §2.5.

In order to prove Proposition 3.15, i.e. that, in case G and u are split, the coefficients of the polynomials $|\mathcal{P}_u^F|$ and $|(\mathcal{P}_u^0)^F|$ are given by the Betti numbers of the varieties $\mathcal{P}_u$ and $\mathcal{P}_u^0$, we require a purity result for these varieties. In §2.4 we deduce such a result from a well-known purity result of T. A. Springer [26] for the variety $\mathcal{B}_u$ of Borel subgroups of G that contain u. This deduction also requires results of W. Borho and R. MacPherson ([3]) about the varieties $\mathcal{P}_u$ and $\mathcal{P}_u^0$.

By $k(U^F, G^F)$ we denote the number of U^F-conjugacy classes in G^F. To prove Theorem 4.5 we adapt the arguments in [1] to express $k(U^F, G^F)$ in terms of the sizes of the sets $(\mathcal{P}_u^0)^F$ for $u \in U^F$. The independence of the parameterization of the unipotent G^F-conjugacy classes means that, in a sense, this expression does not depend on q. This allows us to deduce Theorem 4.5 from Theorem 3.10.

Let P and Q be associated F-stable parabolic subgroups of G, i.e. P and Q have Levi subgroups which are conjugate in G. Let $\mathcal{P}$ and $\mathcal{Q}$ be the corresponding generalized flag varieties of P and Q, respectively. In Corollary 3.5 we show that for $u \in G^F$ unipotent, we have $|\mathcal{P}_u^F| = |\mathcal{Q}_u^F|$ and $|(\mathcal{P}_u^0)^F| = |(\mathcal{Q}_u^0)^F|$. Further, let U and V be the unipotent radicals of P and Q, respectively. As a consequence of the expressions that we get for the polynomials in Theorem 4.5, we show in Corollary 4.7, that the two polynomials in q given by $k(U^F, G^F)$ and $k(V^F, G^F)$ are equal. This essentially follows from the fact that the Harish-Chandra induction functor R_L^G does not depend on the choice of an F-stable parabolic subgroup of G containing L as a Levi subgroup and due to the fact that the Richardson classes of associated parabolic subgroups coincide.

We note that the assumption that the centre of G is connected is only really required so that the parameterization of the unipotent G^F-conjugacy classes is independent of q. This

means that many of the results in this paper are valid without this assumption given an appropriate statement. For example, see Remark 3.12. In Example 4.10 we indicate how in case G has disconnected centre the number of U^F-conjugacy classes in G^F is given by a set of polynomials in q depending on the congruence class of q with respect to some positive integer.

In an appendix to this paper, we give an elementary combinatorial proof that $|(\mathcal{P}_u^0)^F|$ is given by a polynomial in q in the case $G = \mathrm{GL}_n$. Consequently, we obtain an elementary proof of Theorem 4.5 in the case $G = \mathrm{GL}_n$.

As general references on finite groups of Lie type, we refer the reader to the books by Carter [4] and Digne–Michel [6].

2. Preliminaries

For the statements of the main results of this paper we require an axiomatic formalism for connected reductive algebraic groups; this is introduced in §2.2. In other parts of the sequel we do not require this axiomatic setup and we use the notation given in the following subsection instead. In each subsection, we state which setup we are using.

2.1. **General notation for algebraic groups.** In this section we introduce various pieces of notation that we require in the sequel.

First we fix some general group theoretic notation. For a group G, a subgroup H of G and $x \in G$ we write: $Z(G)$ for the centre of G; $N_G(H)$ for the normalizer of H in G; $C_G(x)$ for the centralizer of x in G; $G \cdot x$ for the conjugacy class of x in G; and we write $^xH = xHx^{-1}$. If G is finite and p is a prime, then we write $|G|_p$ for the p-part of the order of G, and $|G|_{p'}$ for the p'-part of the order of G.

Now we give some notation for connected reductive algebraic groups that we use in the sequel. Let G be a connected reductive algebraic group over the algebraic closure of a finite field $\mathbb{F}_q$, where q is a prime power. The variety of unipotent elements of G is denoted by G_{uni}. For a closed subgroup H of G we write H° for the identity component of H and $R_{\mathrm{u}}(H)$ for the unipotent radical of H. Given $x \in G$ we write $A(x) = C_G(x)/C_G(x)^\circ$ for the component group of the centralizer of x.

Let T be a maximal torus of G and let B be a Borel subgroup of G containing T. We write Ψ for the root datum of G with respect to T; so Ψ is a quadruple $(X, \Phi, \check{X}, \check{\Phi})$, where X is the character group of T, Φ is the root system of G with respect to T, $\check{X}$ is the cocharacter group of T and $\check{\Phi}$ is the set of coroots of G with respect to T. Let Π (resp. Φ^+) be the base of Φ (resp. the subset of positive roots) determined by B. For a subset J of Π, the standard parabolic subgroup $P = P_J$ is defined to be generated by B and the root subgroups $U_{-\alpha}$ for $\alpha \in J$. The unipotent radical of P is denoted by $U = R_{\mathrm{u}}(P)$. We write $L = L_J$ for the unique Levi subgroup of P that contains T, i.e. L is the standard Levi subgroup of P, see [6, Prop. 1.17]. The Weyl group of G is denoted by W and we write W_L for the Weyl group of L. As usual, $l(w)$ denotes the length of $w \in W$ with respect to the set of Coxeter generators determined by Π.

For $\beta \in \Phi^+$ write $\beta = \sum_{\alpha \in \Pi} c_{\alpha,\beta}\alpha$ with $c_{\alpha,\beta} \in \mathbb{Z}_{\geq 0}$. We recall that a prime p is said to be *bad* for the root system Φ if it divides $c_{\alpha,\beta}$ for some α and β, else it is called *good* for Φ; we say p is good for G if it is good for Φ.

3

Now suppose G is defined over $\mathbb{F}_q$, where q is a power of p, and let $F : G \to G$ be the corresponding Frobenius morphism of G. We write G^F for the finite group of F-fixed points of G; likewise for any F-stable subvariety of G. Assume that B is F-stable (such a B exists, see [6, 3.15]) so that T is a *maximally split* maximal torus of G. For each $w \in W$ we let T_w be an F-stable maximal torus of G obtained by twisting T by w, see [6, 3.24].

We now recall some notation regarding the representation theory of the finite group of Lie type G^F. To simplify notation we often omit the superscript F in places where it should strictly be written, so for example we write 1_G for the trivial character of G^F and we denote the regular character of G^F by χ_G. Given an F-stable subgroup H of G, we write Ind_H^G for the induction functor from characters of H^F to characters of G^F. For an F-stable Levi subgroup of G, we write R_L^G for the Deligne–Lusztig induction functor from characters of L^F to characters of G^F (see [6, §11]). If L is a Levi subgroup of an F-stable parabolic subgroup P of G, then we recall that R_L^G is the Harish-Chandra induction functor (see [6, §6]). For $w \in W$ we write $\operatorname{Irr}(T_w^F)$ for the character group of T_w^F.

In some parts of this paper we consider l-adic cohomology groups. Given a variety V defined over $\mathbb{F}_q$ we write $H^i(V, \overline{\mathbb{Q}}_l)$ for the ith l-adic cohomology group of V, where l is a prime not dividing q. We write $H_c^i(V, \overline{\mathbb{Q}}_l)$ for the l-adic cohomology with compact support groups. Recall that in case V is projective, the cohomology groups $H^i(V, \overline{\mathbb{Q}}_l)$ and $H_c^i(V, \overline{\mathbb{Q}}_l)$ coincide.

2.2. **Axiomatic setup for connected reductive algebraic groups.** In order to be able to state the results indicated in the introduction precisely, we use an axiomatic formalism for connected reductive algebraic groups, following [8, §4]. The idea is that a tuple of combinatorial objects is used to define a family of connected reductive groups indexed by prime powers. We refer the reader to [6, §0, §3] for some of the results used below.

Let $\Psi = (X, \Phi, \check{X}, \check{\Phi})$ be a root datum. Then given a finite field $\mathbb{F}_q$, the root datum Ψ determines a connected reductive algebraic group G over $\overline{\mathbb{F}}_q$ and a maximal torus T of G such that Ψ is the root datum of G with respect to T; moreover, G is unique up to isomorphism and T is unique up to conjugation in G.

Now let Π be a base for Φ; this determines a Borel subgroup B of G containing T. Further, B is determined up to conjugacy in G.

Let $F_0 : X \to X$ be an automorphism of finite order such that $F_0(\Phi) = \Phi$, $F_0(\Pi) = \Pi$ and $F_0^*(\check{\Phi}) = \check{\Phi}$. Then for any prime power q, the automorphism F_0 defines a Frobenius morphism $F : G \to G$ such that the induced action of F on X is given by $q \cdot F_0$. Further, B and T are F-stable, so that T is a maximally split maximal torus of G.

Now let J be a subset of Π such that $F_0(J) = J$. Then J determines the standard parabolic subgroup $P = P_J$ of G. If q is a prime power and F is the corresponding Frobenius morphism $q \cdot F_0$ of G, then P is F-stable.

Summing up, the discussion above implies that the quadruple $\Delta = (\Psi, \Pi, F_0, J)$, along with a prime power q determines

- a connected reductive algebraic group G defined over $\mathbb{F}_q$ with corresponding Frobenius morphism F and maximally split F-stable maximal torus T;
- an F-stable Borel subgroup $B \supseteq T$ of G; and
- an F-stable parabolic subgroup $P \supseteq B$.

The connected reductive algebraic group G is unique up to isomorphism defined over $\mathbb{F}_q$; the Borel subgroup B is determined up to conjugacy in G^F; the maximal torus T is determined up to conjugacy in B^F; and (given B) P is uniquely determined.

At some points in the sequel we do not require the parabolic subgroup P. In such situations we only consider the data $\Gamma = (\Psi, \Pi, F_0)$, which along with a prime power q determines everything above except for P.

Remark 2.1. We note that if we do not assume that F_0 stabilizes a base Π of Φ, then the data (Ψ, F_0) and q still determine a connected reductive algebraic group G that is defined over $\mathbb{F}_q$ and an F-stable maximal torus T of G, which is not, in general, maximally split. However, there always exists an F-stable Borel subgroup of G (see [6, 3.15]). Therefore, it does no harm to make the assumption that F_0 stabilizes Π.

The notation we use for G, B, T and P does not reflect the fact that their $\mathbb{F}_q$-structure depends on the choice of a prime power q. Let q be a prime power and m a positive integer, write F for the Frobenius morphism corresponding to q. Then it is not necessarily the case that the Frobenius morphism corresponding to the prime power q^m is F^m, i.e. the definition of G over $\mathbb{F}_{q^m}$ is not necessarily obtained from the $\mathbb{F}_q$-structure by extending scalars. For example, suppose $G = \mathrm{SL}_n$ with definition over $\mathbb{F}_q$ so that G^F is the special unitary group $\mathrm{SU}_n(q^2)$, i.e. F_0 is given by the graph automorphism of the Dynkin diagram of type A_{n-1}. Then the automorphism F_0^2 is the identity, so that the group of $\mathbb{F}_{q^2}$-rational points of G is $G^{F^2} = \mathrm{SL}_n(q^2)$ and not $\mathrm{SU}_n(q^4)$. However, in order to keep the notation short, we choose not to show this dependence on q.

Remark 2.2. Despite the lack of outward exhibition of dependence on q discussed above, in the sequel we wish to allow q to vary and for G, B, T and P to define groups and F a Frobenius morphism of G for each q. For example, this convention is required in order to make sense of statements such as the following: "the number of F-stable unipotent conjugacy classes of G is independent of q", or "the number of conjugates of P^F having non-trivial intersection with a given F-stable conjugacy class of unipotent elements is given by a polynomial in q".

Now we discuss some further information that is determined by the data $\Delta = (\Psi, \Pi, F_0, J)$ and prime power q, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$ is a root datum. First we note that the unipotent radical $U = R_\mathrm{u}(P)$ of the F-stable parabolic subgroup $P = P_J$ of G and the unique Levi subgroup $L = L_J$ of P containing T are determined. Since both P and T are F-stable, so is L. The Weyl group W of G and the Weyl group W_L of L are determined by Δ; further, we note that W and W_L are independent of q. The F-stable twisted tori T_w ($w \in W$) are determined up to conjugacy in G^F. The root lattice of Φ, which is denoted by $\mathbb{Z}\Phi$, is determined by Δ.

Lastly, in this section we discuss two further properties of the group G that are determined by Δ. At some points in the sequel we wish to assume that the centre of G is connected. We note that this being the case for all q corresponds to $X/\mathbb{Z}\Phi$ being torsion free; this is because the character group of $Z(G)$ is $X/\mathbb{Z}\Phi$ modulo its p-torsion subgroup, where q is a power of the prime p. Also at some points we assume that G is simple modulo its centre, we note that this corresponds to Φ being an irreducible root system.

2.3. **On the unipotent conjugacy classes of G^F.** In this subsection we use the axiomatic setup from §2.2. In particular, we fix a triple $\Gamma = (\Psi, \Pi, F_0)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$, so that for each choice of a prime power q we obtain a connected reductive group G defined over $\mathbb{F}_q$; we write $F : G \to G$ for the corresponding Frobenius morphism of G. We use the convention discussed in Remark 2.2 to vary q. Further, any prime power that we consider is assumed to be a power of a good prime for Φ.

It is known that the parameterization of the unipotent classes of G and the structure of the associated component groups $A(u) = C_G(u)/C_G(u)^\circ$ for $u \in G_{\mathrm{uni}}$ is independent of q (cf. [16], [17], [14]). We would like a similar statement for the F-stable unipotent classes of G, and for the unipotent G^F-classes.

There is a parameterization of the F-stable unipotent classes as follows (see [20], [12], and also [8, §4]). There is a finite set E depending only on Γ (and not on q) so that there is a map $E \to G^F_{\mathrm{uni}}$ written $e \mapsto u_e$ so that $\{u_e \mid e \in E\}$ is a complete set of representatives for the F-stable unipotent classes in G. Therefore, the F-stable conjugacy classes are parameterized by E and this parameterization is independent of q.

In order to get a parameterization of the unipotent G^F-conjugacy classes we require some additional assumptions. We assume that $X/\mathbb{Z}\Phi$ is torsion free, so that the centre of G is connected, and Φ is irreducible, so that G is simple modulo its centre.

With these additional assumptions, there is a collection of groups $\{A_e \mid e \in E\}$ (not depending on q) such that the group of components $A(u_e)$ of u_e is isomorphic to A_e for every $e \in E$ and the induced action of F on $A(u_e)$ is trivial. Consequently, for $e \in E$, the G^F-conjugacy classes in $(G \cdot u_e)^F$ are in correspondence with the conjugacy classes of A_e, cf. [27, I, 2.7]. So the unipotent G^F-classes are parameterized by pairs (e, c), where $e \in E$ and c is a conjugacy class of A_e. Moreover, this parameterization is independent of q.

These results largely follow from work of T. Shoji on split elements. Following [20, §5], an element $u \in G^F_{\mathrm{uni}}$ is called *split* provided each irreducible component of $\mathcal{B}_u$ (see §2.4 for a definition of $\mathcal{B}_u$) is stable under the action of F. If q is a power of a good prime for Φ, then split elements exist in each F-stable unipotent G-conjugacy class and are unique up to G^F-conjugacy with one exception, see [20, Rem. 5.1]. If G is of type E_8, $q \equiv -1 \mod 3$, and C is the class $E_8(b_6)$ in the Bala–Carter labeling (this class is $D_8(a_3)$ in Mizuno's labeling [15]), then there are no split elements in C^F. If u is split, then F acts trivially on $A(u)$, see [20]. The one case for G of type E_8 where there is no split element can be dealt with explicitly, see [12].

Thus we have the following result, where we are using the convention discussed in Remark 2.2 to allow q to vary. This proposition is also stated in [8, §4.1].

Proposition 2.3. *Fix the data* $\Gamma = (\Psi, \Pi, F_0)$, *where* $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. *Assume that* Φ *is irreducible and* $X/\mathbb{Z}\Phi$ *is torsion free. For a prime power* q, *let* G *be the connected reductive algebraic group and* F *the Frobenius morphism determined by* Γ. *Then the parameterization of the unipotent conjugacy classes in* G^F *is independent of* q, *for* q *a power of a good prime for* Φ.

We now turn our attention to showing that Proposition 2.3 remains true when we remove the assumption that G is simple modulo its centre, i.e. that the root system Φ is possibly reducible. At the end of this subsection we briefly discuss what happens when G has disconnected centre.

We begin by assuming that G is semisimple and of adjoint type, equivalently that $X = \mathbb{Z}\Phi$. In this case the root system Φ has irreducible components on which the automorphism F_0 acts. We may write Φ as a disjoint union $\Phi = \Phi_1 \cup \cdots \cup \Phi_s$ of F_0-stable root systems, where the irreducible components of each Φ_i form a single orbit under the action of F_0. This gives rise to a direct product decomposition $G = G_1 \times \cdots \times G_s$, where each G_i is a semisimple algebraic group of adjoint type with root system Φ_i; moreover each G_i is F-stable. Now for fixed i, the root system Φ_i is the disjoint union of irreducible root systems of the same type; let Υ_i be a root system of this type. Then G_i is a direct product $G_i = H_i \times \cdots \times H_i$ where H_i is a simple algebraic group of adjoint type with root system Υ_i. Let l_i be the number of factors H_i in the direct product decomposition of G_i. Then we see that $G_i^F \cong H_i^{F^{l_i}}$, so that the $\mathbb{F}_q$-rational points of G_i are in correspondence with the $\mathbb{F}_{q^{l_i}}$-rational points of H_i. It follows that the unipotent G_i^F-conjugacy classes have the same parameterization as the unipotent $H_i^{F^{l_i}}$-conjugacy classes, i.e. there is a finite set E_i and for each $e \in E_i$ there is a group $A_{i,e}$ such that the unipotent G_i^F-conjugacy classes are given by pairs (e, c) where $e \in E_i$ and c is a conjugacy class of $A_{i,e}$. More precisely, there exists $u_{i,e} \in G_i$ for $e \in E_i$ such that the F-stable G_i-conjugacy classes are precisely the classes $G_i \cdot u_{i,e}$ and the component group $A(u_{i,e})$ of the centralizer of $u_{i,e}$ is $A_{i,e}$. Let $E = E_1 \times \cdots \times E_s$ and for $e = (e_1, \ldots, e_s) \in E$ let $A_e = A_{1,e_1} \times \cdots \times A_{s,e_s}$. Then we see that the unipotent G^F-conjugacy classes are parameterized by pairs (e, c), where $e \in E$ and c is a conjugacy class of A_e. For $e \in E$, we let u_e be a representative of the F-stable unipotent G-class, such that $A(u_e) \cong A_e$ and F acts trivially on $A(u_e)$.

We now consider the case where the centre of G is not necessarily trivial, but is connected. In this case we let $\hat{G}$ be the semisimple adjoint group of the same type as G and let $\phi : G \to \hat{G}$ be the natural map. The Frobenius morphism F of G induces a Frobenius morphism of $\hat{G}$, which we also denote by F. We note that ϕ induces a bijective morphism $G_{\mathrm{uni}} \to \hat{G}_{\mathrm{uni}}$, and this induces a bijection between the F-stable unipotent conjugacy classes of G and those of $\hat{G}$. Let $u \in G_{\mathrm{uni}}^F$ be a representative of an F-stable unipotent G-conjugacy class so that $\phi(u) = u_e$ for some $e \in E$ as above. We have the exact sequence of algebraic groups

(2.4) $$\{1\} \to Z(G) \to C_G(u) \to C_{\hat{G}}(\phi(u)) \to \{1\}.$$

Further we note that F commutes with the maps in this sequence. Since taking component groups defines a right exact functor on the category of algebraic groups over $\overline{\mathbb{F}}_q$ and $Z(G)$ is connected, we get an exact sequence of finite groups

$$\{1\} \to A(u) \to \hat{A}(\phi(u)) \to \{1\}.$$

Moreover, F commutes with this isomorphism. Therefore, it follows that ϕ induces a bijection between the unipotent G^F-conjugacy classes and the unipotent $\hat{G}^F$-conjugacy classes.

The discussion above gives the following generalization of Proposition 2.3.

Proposition 2.5. *Fix the data* $\Gamma = (\Psi, \Pi, F_0)$, *where* $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. *Assume that* $X/\mathbb{Z}\Phi$ *is torsion free. For a prime power* q, *let* G *be the reductive algebraic group and* F *the Frobenius morphism determined by* Γ. *Then the parameterization of the unipotent conjugacy classes in* G^F *is independent of* q, *for* q *a power of a good prime for* Φ.

Remark 2.6. The discussion proving Proposition 2.5 gives a parameterization of the unipotent G^F-conjugacy classes given by pairs (e, c), where $e \in E$ and c is a conjugacy class of A_e. We may let $u = u_{e,c} \in G_{\mathrm{uni}}^F$ be a representative of this conjugacy class. We now use the

convention in Remark 2.2 to vary q. In general, as we vary q, the representative u changes. For the statement of results in Sections 3 and 4, we use the convention that when we fix a representative of a unipotent class and let q vary, then it is understood that u also changes.

To finish this subsection we briefly consider the situation when G has disconnected centre. As we do not require this case in the sequel, the discussion below is brief and omits details.

Suppose that G has disconnected centre. Let $\hat{G}$ be the semisimple adjoint group of the same type as G and let $\phi : G \to \hat{G}$ be the natural map. We still have a bijective morphism $G_{\mathrm{uni}} \to \hat{G}_{\mathrm{uni}}$ induced by ϕ and this affords a bijection between the F-stable unipotent classes in G and $\hat{G}$. The arguments above using the exact sequence (2.4) imply that taking the quotient of G by $Z(G)^\circ$ does not affect the unipotent G^F-conjugacy classes. Therefore, we may assume that $Z(G)$ is finite.

Let $u \in G_{\mathrm{uni}}^F$ be such that $\phi(u) = u_e$ for some $e \in E$ as above. We still have the short exact sequence (2.4). When we take component groups, we get the exact sequence

$$Z(G) \to A(u) \to \hat{A}(\phi(u)) \to \{1\},$$

and the action of F commutes with the maps in this exact sequence. Let Z be the image of $Z(G)$ in $A(u)$. Then we have $A(u)/Z \cong \hat{A}(\phi(u))$ and Z is stable under F-conjugation by $A(u)$. It follows that the F-conjugacy classes of $A(u)$ are given by pairs (c, d), where c is a conjugacy class of $\hat{A}(\phi(u))$ with representative $xZ \in A(u)/Z \cong \hat{A}(\phi(u))$, and d is an F-conjugacy class of $C_{A(u)}(x)$ in Z. This in turn says that the G^F-conjugacy classes in $(G \cdot u)^F$ are parameterized by pairs (c, d) as above. In general, this parameterization depends on q but only up to congruences of q modulo some positive integer.

We illustrate this splitting of conjugacy classes in the disconnected centre case with a simple example.

Example 2.7. Suppose $G = \mathrm{SL}_3$ with the standard definition over $\mathbb{F}_q$. Then G has three unipotent conjugacy classes labeled by the partitions (3), $(2,1)$ and $(1,1,1)$ of 3. The regular unipotent class corresponds to the partition (3) and a split representative is

$$u = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

One can easily calculate the centralizer of u, and deduce that $A(u)$ is the group of cube roots of unity in $\overline{\mathbb{F}}_q$ and the action of F on $A(u)$ is the qth power map. If q is congruent to 1 modulo 3, then the action of F on $A(u)$ is trivial and so there are three F-conjugacy classes in $A(u)$. If q is congruent to -1 modulo 3, then there is a single F-conjugacy class in $A(u)$ and if q is a power of 3, then $A(u)$ is the trivial group and thus is a single F-conjugacy class. It follows that the G^F-conjugacy classes in $(G \cdot u)^F$ depend on the congruence class of q modulo 3. We note that in case $q \equiv 0 \bmod 3$, the centre of G is connected and in this case it follows from the general theory that the parameterization of the unipotent G^F-conjugacy classes does not depend on q.

2.4. **On purity of generalized flag varieties.** In this subsection we use the notation from §2.1; we do not require the axiomatic formalism from §2.2.

Let $\mathcal{B}$ be the flag variety of G consisting of all Borel subgroups of G. Fix a parabolic subgroup P of G. Let $\mathcal{P} = \{^g P \mid g \in G\}$ be the corresponding *generalized flag variety* consisting of all the G-conjugates of P.

For a unipotent element $u \in G$, we consider the fixed point subvarieties $\mathcal{B}_u = \{B' \in \mathcal{B} \mid u \in B'\}$ of $\mathcal{B}$ and $\mathcal{P}_u = \{P' \in \mathcal{P} \mid u \in P'\}$ of $\mathcal{P}$. We also consider the related subvariety $\mathcal{P}_u^0 = \{P' \in \mathcal{P} \mid u \in R_u(P')\}$ of $\mathcal{P}_u$. Note that for $P = B$ we have $\mathcal{P}_u = \mathcal{P}_u^0 = \mathcal{B}_u$. We can identify the variety $\mathcal{B}_u$ with a fibre of Springer's resolution of the singularities of the unipotent variety G_{uni} of G. The fixed point varieties $\mathcal{P}_u$ can be viewed as fibres of *partial resolutions* of G_{uni}, and have been studied by Borho–MacPherson [3] and Spaltenstein [24].

Let V be a variety defined over $\mathbb{F}_q$ with Frobenius morphism F corresponding to the $\mathbb{F}_q$-structure. We recall that V is called *pure* (or said to satisfy the *purity condition*), if the eigenvalues of F on the l-adic cohomology groups $H_c^i(V, \overline{\mathbb{Q}}_l)$ are algebraic integers of absolute value $q^{i/2}$.

Let $u \in G_{\mathrm{uni}}^F$. In [26], Springer showed that despite the fact that the fixed point varieties $\mathcal{B}_u$ are not smooth, they are pure. We require this purity condition also for the varieties $\mathcal{P}_u$ and $\mathcal{P}_u^0$.

Let L be the unique Levi subgroup of P containing T. It follows from a result of Borho–MacPherson [3, Cor. 2.8] (see also [24, Thm. 1.2]) that for each i there is an isomorphism of $\overline{\mathbb{Q}}_l$-spaces

$$(2.8) \qquad H^i(\mathcal{P}_u, \overline{\mathbb{Q}}_l) \cong H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)^{W_L},$$

where $H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)^{W_L}$ is the subspace of $H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)$ of W_L-invariants (where the action of W on $H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)$ is given by the action of W defined by Springer [26] multiplied with the sign character of W). The isomorphism in (2.8) is induced by the natural map $\mathcal{B}_u \to \mathcal{P}_u$ (cf. [24, Thm. 1.2]), which is clearly F-equivariant. Therefore, the isomorphism in (2.8) is compatible with the induced F-actions on both sides. As a consequence, the eigenvalues of F on $H^i(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$ are algebraic integers of modulus $q^{i/2}$ so that $\mathcal{P}_u$ is pure.

Since P and T are F-stable, so is L and the induced action of F on L is a Frobenius morphism. Whence F acts on $\mathcal{B}(L)$, the variety of Borel subgroups of L. Let $d_0 = \dim \mathcal{B}(L)$. Since $\mathcal{B}(L)$ is smooth, and $H^{2d_0}(\mathcal{B}(L), \overline{\mathbb{Q}}_l) \cong \overline{\mathbb{Q}}_l$, the eigenvalue of F on this one-dimensional space is q^{d_0}. Thanks to [3, Thm. 3.3, Cor. 3.4(b)], we have an isomorphism of $\overline{\mathbb{Q}}_l$-spaces

$$(2.9) \qquad H^{i-2d_0}(\mathcal{P}_u^0, \overline{\mathbb{Q}}_l) \otimes H^{2d_0}(\mathcal{B}(L), \overline{\mathbb{Q}}_l) \cong H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)^{\epsilon W_L},$$

for each i, where $H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)^{\epsilon W_L}$ is the subspace of $H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)$ on which W_L acts via the sign representation ϵ (i.e., the subspace of anti-invariants). Further, the isomorphism in (2.9) is F-equivariant. By Springer's purity result, the eigenvalues of F on $H^i(\mathcal{B}_u, \overline{\mathbb{Q}}_l)^{\epsilon W_L}$ are algebraic integers of modulus $q^{i/2}$. Consequently, the eigenvalues of F on $H^{i-2d_0}(\mathcal{P}_u^0, \overline{\mathbb{Q}}_l)$ are algebraic integers of modulus $q^{(i-2d_0)/2}$ for all i. It follows that $\mathcal{P}_u^0$ is pure.

2.5. Deligne–Lusztig generalized characters and Green functions.

For this subsection we use the axiomatic formalism given in §2.2. We fix the triple $\Gamma = (\Psi, \Pi, F_0)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$, so for each prime power q we have a connected reductive algebraic group G defined over $\mathbb{F}_q$ with Frobenius morphism F. Further, we have a maximal torus T of G and the Weyl group W of G with respect to T. We recall from §2.1 that for a twisted torus T_w ($w \in W$), we write $R_{T_w}^G$ for the Deligne–Lusztig induction functor from characters of T_w^F

to characters of G^F. In this subsection we recall some known results about the values of $R_{T_w}^G(\theta)$ on unipotent elements of G^F, where $\theta \in \mathrm{Irr}(T_w^F)$.

Let $w \in W$ and $\theta \in \mathrm{Irr}(T_w^F)$. We begin by recalling that as a function $G_{\mathrm{uni}}^F \to \overline{\mathbb{Q}}$ the restriction $R_{T_w}^G(\theta)$ to G_{uni}^F does not depend on θ, see [4, Cor. 7.2.9]. The restriction of $R_{T_w}^G(\theta)$ to G_{uni}^F is called a *Green function* and is denoted by $Q_{T_w}^G$, see [4, §7.6].

Suppose q is a power of a good prime for Φ and assume that $X/\mathbb{Z}\Phi$ is torsion free (i.e. the centre of G is connected), so that Proposition 2.5 applies. With these assumptions, work of Shoji [20, Prop. 6.1] tells us that the Green functions $Q_{T_w}^G$ evaluated on a unipotent class of G^F are given by certain polynomials in q whose coefficients are independent of q, if G does not have a simple component of type E_8. If G has a simple component of type E_8, then for $u \in G_{\mathrm{uni}}^F$, the value of $Q_{T_w}^G(u)$ is given by one of two polynomials in q depending on whether q is congruent 1 or -1 modulo 3, see [20, Rem. 6.2].

Remark 2.10. For G simple of type E_8 we only require two polynomials in case u lies in the conjugacy class with Bala–Carter label $E_8(b_6)$, see [20, Rem. 5.1]. This is precisely the conjugacy class for which there is no split element if q is congruent to -1 mod q, as mentioned in §2.3. For reductive G the two polynomials are only required in case there is a simple component H of G of type E_8, such that the size of the F-orbit of H is odd and the projection of u into H belongs to the class with Bala–Carter label $E_8(b_6)$. For, if the F-orbit of H is of even size $2m$, then the group of F-stable points of the direct product of the simple groups in this orbit is a finite simple group of type E_8 over the field $\mathbb{F}_{q^{2m}}$, so that there does exist a split element (since $q^{2m} \equiv 1 \mod 3$).

Remark 2.11. In case q is a power of a bad prime for G, it is conjectured that the Green functions $Q_{T_w}(u)$ are also given by polynomials in q; this has been verified in many cases. In general, these polynomials differ from those for good characteristic.

2.6. **Two standard lemmas.** In this subsection we recall two standard lemmas that we require in the sequel. The first of these concerns a condition on a rational function that forces it to be a polynomial, we include a proof of this well-known result for the reader's convenience.

Lemma 2.12. *Let $f(z) \in \mathbb{Q}(z)$ be a rational function. Suppose that there are infinitely many $n \in \mathbb{Z}$ such that $f(n) \in \mathbb{Z}$. Then $f(z) \in \mathbb{Q}[z]$ is in fact a polynomial.*

Proof. We may write $f(z) = g(z) + \frac{h(z)}{k(z)}$, where $g(z), h(z), k(z) \in \mathbb{Q}[z]$ and the degree of $h(z)$ is strictly less than that of $k(z)$. Suppose for a contradiction that $h(z) \neq 0$. We can find a positive integer N such that $Ng(z) \in \mathbb{Z}[z]$. Since $f(n) \in \mathbb{Z}$ for infinitely many $n \in \mathbb{Z}$, there exists such n for which $0 < \frac{h(n)}{k(n)} < 1/N$. But then we have $Nf(n) = Ng(n) + N\frac{h(n)}{k(n)}$, and the left hand side is an integer, whereas the right hand side cannot be an integer. This contradiction shows that $h(z) = 0$, so that $f(z) = g(z) \in \mathbb{Q}[z]$, as required. $\square$

For the next lemma we refer the reader to §2.4 for the definition of a pure variety. Using the Grothendieck trace formula (e.g. see [6, Thm. 10.4]), Lemma 2.13 can be proved with standard arguments, see for example [2, §5].

Lemma 2.13. *Let V be a pure variety defined over a finite field $\mathbb{F}_q$. Let F be the Frobenius morphism corresponding to the $\mathbb{F}_q$-structure on V. Suppose there exists $g(z) \in \mathbb{Q}[z]$ such*

that $|V^{F^s}| = g(q^s)$ for any power q^s. Then

$$g(z) = \sum_{i=1}^{\dim V} \dim H_c^{2i}(V, \overline{\mathbb{Q}}_l) z^i.$$

In particular, $g(z) \in \mathbb{Z}[z]$ and the coefficients in $g(z)$ are positive integers. Further, we have $H_c^i(V, \overline{\mathbb{Q}}_l) = \{0\}$ for i odd, and all the eigenvalues of F^s on $H_c^{2i}(V, \overline{\mathbb{Q}}_l)$ are q^{is} for all $i = 0, \ldots, \dim V$ and all $s \in \mathbb{Z}_{\geq 1}$.

3. Rational points of fixed point subvarieties of generalized flag varieties

In this section we prove Theorem 3.10 and Proposition 3.15. The proofs of these results are contained in §3.2 and §3.3. Theorem 3.10 is a consequence of Proposition 3.4, which is proved by combining well-known results from the representation theory of finite groups of Lie type.

3.1. Fixed point subvarieties of flag varieties.

In this subsection we use the notation given in §2.1 and also the notation from §2.4; we do not require the axiomatic setup from §2.2. In particular, B is an F-stable Borel subgroup of G containing an F-stable maximal torus T, and P is an F-stable parabolic subgroup of G containing B. The unipotent radical of P is denoted by U. Note that U is also F-stable.

The Frobenius morphism F acts on the variety $\mathcal{P}$ of conjugates of P. For $u \in G_{\text{uni}}^F$ this induces an action of F on the fixed point varieties $\mathcal{P}_u$ and also on $\mathcal{P}_u^0$. Therefore, we may consider the F-fixed points of each of these varieties: $\mathcal{P}^F$, $\mathcal{P}_u^F$ and $(\mathcal{P}_u^0)^F$. We may identify $\mathcal{P}$ with G/P, because $P = N_G(P)$. Then by [6, Cor. 3.13] we identify $\mathcal{P}^F$ with G^F/P^F, which in turn we can identify with $\{{}^g P^F \mid g \in G^F\}$, because $N_{G^F}(P^F) = P^F$. This allows us to identify $\mathcal{P}_u^F$ with $\{{}^g P^F \mid g \in G^F, u \in {}^g P^F\}$. In a similar way, we identify $(\mathcal{P}_u^0)^F$ with $\{{}^g P^F \mid g \in G^F, u \in {}^g U^F\}$ which in turn can be identified with $\{{}^g U^F \mid g \in G^F, u \in {}^g U^F\}$.

For an F-stable subgroup H of G and for $x \in G^F$ we define

$$f_H^G(x) = |\{{}^g H^F \mid g \in G^F, x \in {}^g H^F\}|.$$

To keep the notation short, we do not show the dependence on F in the notation $f_H^G(x)$. Note that if $x \in G^F$ is not conjugate to an element in H^F, then $f_H^G(x) = 0$.

The following lemma is a consequence of the discussion above.

Lemma 3.1. *Let $u \in G_{\text{uni}}^F$. Then we have*

(i) $|\mathcal{P}_u^F| = f_P^G(u)$;
(ii) $|(\mathcal{P}_u^0)^F| = f_U^G(u)$.

Let L be the unique Levi subgroup of P containing T. Since P and T are F-stable, so is L. For the statements of the next lemmas we recall that W_L denotes the Weyl group of L and T_w is a maximal torus obtained from T by twisting by $w \in W$.

Lemma 3.2. *Let $u \in G_{\text{uni}}^F$. Then we have*

$$f_P^G(u) = \frac{1}{|W_L|} \sum_{w \in W_L} Q_{T_w}^G(u).$$

11

Proof. First note that $f_P^G(u)$ is the value at u of the permutation character $\mathrm{Ind}_P^G(1_P)$ of G^F on the cosets of P^F. Now $\mathrm{Ind}_P^G(1_P)$ is the trivial character 1_L of L^F Harish-Chandra induced to G^F, i.e. as a function $G_{\mathrm{uni}}^F \to \overline{\mathbb{Q}}$ we have

$$f_P^G = R_L^G(1_L),$$

where R_L^G is the Harish-Chandra induction functor. By [6, Prop. 12.13] the trivial character 1_L of L^F is given in terms of Deligne–Lusztig generalized characters as follows

$$1_L = \frac{1}{|W_L|} \sum_{w \in W_L} R_{T_w}^L(1_{T_w}),$$

where $R_{T_w}^L$ is the Deligne–Lusztig induction functor. Applying the Harish-Chandra induction functor R_L^G to $R_{T_w}^L(1_{T_w})$ gives the corresponding generalized character $R_{T_w}^G(1_{T_w})$ for G^F, cf. [6, Prop. 4.7]. Therefore, we have

$$R_L^G(1_L) = \frac{1}{|W_L|} \sum_{w \in W_L} R_{T_w}^G(1_{T_w}).$$

As discussed in §2.5 the restriction of the virtual character $R_{T_w}^G(1_{T_w})$ to the unipotent elements u of G^F is just a Green function $Q_{T_w}^G$ of G^F. Thus we obtain

$$f_P^G(u) = \frac{1}{|W_L|} \sum_{w \in W_L} Q_{T_w}^G(u),$$

as claimed. $\qquad\square$

The formula in Lemma 3.2 can also be found in [13, Lem. 2.3]. Our next result is proved in a similar way to Lemma 3.2.

Lemma 3.3. *Let $u \in G_{\mathrm{uni}}^F$. Then we have*

$$f_U^G(u) = \frac{1}{|L^F|_p|W_L|} \sum_{w \in W_L} (-1)^{l(w)} Q_{T_w}^G(u).$$

Proof. First note that $|L^F| \cdot f_U^G(u)$ is the value at u of the permutation character $\mathrm{Ind}_U^G(1_U)$ of G^F on the cosets of U^F, because $N_{G^F}(U^F) = P^F = L^F U^F$. Since U^F is normal in P^F, we see that $\mathrm{Ind}_U^G(1_U)$ is the regular character χ_L of L^F Harish-Chandra induced to G^F, i.e.,

$$|L^F| \cdot f_U^G = R_L^G(\chi_L).$$

By [6, Cor. 12.14] the regular character χ_L of L^F is given by

$$\chi_L = \frac{1}{|W_L|} \sum_{w \in W_L} \dim(R_{T_w}^L(1_{T_w})) R_{T_w}^L(\chi_{T_w}).$$

Using [6, Cor. 12.9, Rem. 12.10], we have

$$\chi_L = |L^F|_{p'} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} |T_w^F|^{-1} R_{T_w}^L(\chi_{T_w}).$$

Since $\chi_{T_w} = \sum_{\theta \in \mathrm{Irr}(T_w^F)} \theta$, we have

$$\chi_L = |L^F|_{p'} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} |T_w^F|^{-1} \sum_{\theta \in \mathrm{Irr}(T_w^F)} R_{T_w}^L(\theta).$$

12

Thus, the regular character of L^F is a $\mathbb{Q}$-linear combination of generalized Deligne–Lusztig characters, $R^L_{T_w}(\theta)$. Harish-Chandra induction applied to $R^L_{T_w}(\theta)$ gives the corresponding generalized character $R^G_{T_w}(\theta)$ for G^F. Therefore, we have

$$R^G_L(\chi_L) = |L^F|_{p'} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} |T^F_w|^{-1} \sum_{\theta \in \mathrm{Irr}(T^F_w)} R^G_{T_w}(\theta).$$

On unipotent elements u of G^F the virtual character $R^G_{T_w}(\theta)$ is independent of the choice of the character θ of T^F_w and is just a Green function $Q^G_{T_w}$, as discussed in §2.5. Therefore, we have that $R^G_{T_w}(\theta)(u) = R^G_{T_w}(1_{T_w})(u) = Q^G_{T_w}(u)$. Thus we obtain

$$f^G_U(u) = |L^F|_{p'} \cdot \frac{1}{|L^F|} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} |T^F_w|^{-1} | \mathrm{Irr}(T^F_w)| Q^G_{T_w}(u)$$

$$= \frac{1}{|L^F|_p} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} Q^G_{T_w}(u),$$

as claimed. □

Combining Lemmas 3.1–3.3 we get the following proposition.

Proposition 3.4. *Let P be an F-stable parabolic subgroup of G containing an F-stable maximal torus T of G. Let L be the Levi subgroup of P containing T and let $u \in G^F_{\mathrm{uni}}$. Then*

(i)
$$|\mathcal{P}^F_u| = \frac{1}{|W_L|} \sum_{w \in W_L} Q^G_{T_w}(u); \ and$$

(ii)
$$|(\mathcal{P}^0_u)^F| = \frac{1}{|L^F|_p |W_L|} \sum_{w \in W_L} (-1)^{l(w)} Q^G_{T_w}(u).$$

We note that the special case $\mathcal{P} = \mathcal{B}$ of Proposition 3.4 is well-known: $|\mathcal{B}^F_u| = Q^G_T(u) = R^G_T(1_T)(u)$, e.g. see [26, §5].

We recall that two parabolic subgroups of G are called *associated* if they have Levi subgroups that are conjugate in G. The formulas for $|\mathcal{P}^F_u|$ and $|(\mathcal{P}^0_u)^F|$ given in Proposition 3.4 depend only on the Levi subgroup L and not on the parabolic subgroup containing L; this is due to the fact that the Harish-Chandra induction functor R^G_L does not depend on the choice of parabolic subgroup containing L that is used to define it, [6, Prop. 6.1]. Therefore, we deduce the following corollary; we note that this was observed also by G. Lusztig, see [22, II 4.16].

Corollary 3.5. *Let P and Q be associated F-stable parabolic subgroups of G and let $\mathcal{P}$ and $\mathcal{Q}$ be the corresponding generalized flag varieties. Let $u \in G^F_{\mathrm{uni}}$. Then we have*

(i) $|\mathcal{P}^F_u| = |\mathcal{Q}^F_u|$; *and*
(ii) $|(\mathcal{P}^0_u)^F| = |(\mathcal{Q}^0_u)^F|$.

Remark 3.6. Assume as in Proposition 3.4. In the special case $P = G$ of Proposition 3.4(i), we recover the following well-known identity

$$\sum_{w \in W} Q^G_{T_w}(u) = |W|,$$

13

for any $u \in G_{\mathrm{uni}}^F$, e.g. see [25, Prop. 5.8].

Let P be an F-stable parabolic subgroup of G with $U = R_{\mathrm{u}}(P)$ and let $\mathcal{P}$ be the corresponding generalized flag variety. Let $u \in G_{\mathrm{uni}}^F$. Suppose that $G \cdot u \cap U = \varnothing$. Then $|(\mathcal{P}_u^0)^F| = 0$ and it follows from Proposition 3.4(ii) that

$$(3.7) \qquad \sum_{w \in W_L} (-1)^{l(w)} Q_{T_w}^G(u) = 0.$$

The special case $P = G$ (and $u \neq 1$) of (3.7) gives

$$(3.8) \qquad \sum_{w \in W} (-1)^{l(w)} Q_{T_w}^G(u) = 0,$$

which is the formula in [20, Prop. 5.2(ii)] for the sign character of W and $1 \neq u \in G_{\mathrm{uni}}^F$ (under the Springer correspondence, the sign representation of W corresponds to the trivial unipotent class in G). Conversely, we can recover (3.7) from the version of (3.8) for "$G = L$" by applying the Harish-Chandra induction functor R_L^G.

Further, the special case $P = G$ and $u = 1$ in Proposition 3.4(ii) gives

$$\frac{1}{|W|} \sum_{w \in W} (-1)^{l(w)} Q_{T_w}^G(1) = q^{\dim \mathcal{B}},$$

which is just the formula in [20, Prop. 5.2(i)] again for the sign character of W.

Remark 3.9. Note that $\mathcal{P}_x$ and $\mathcal{P}_x^0$ are defined for any $x \in G$ (though $\mathcal{P}_x^0$ is empty unless x is unipotent and $G \cdot x \cap R_{\mathrm{u}}(P) \neq \varnothing$). It follows from the proofs of Lemmas 3.1–3.3 that the functions $G^F \to \mathbb{Z}_{\geq 0}$ given by $x \mapsto |\mathcal{P}_x^F|$ and $x \mapsto |(\mathcal{P}_x^0)^F|$ are *uniform*, that is, they are linear combinations of generalized Deligne–Lusztig characters $R_{T_w}^G(\theta)$.

3.2. **Polynomial properties for $|\mathcal{P}_u^F|$ and $|(\mathcal{P}_u^0)^F|$.** In this subsection we use the axiomatic setup given in §2.2. We fix the data $\Delta = (\Psi, \Pi, F_0, J)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. Then for each prime power q we have a connected reductive algebraic group G defined over $\mathbb{F}_q$ with Frobenius morphism F, and we have a parabolic subgroup $P = P_J$ of G which is F-stable. We assume that $X/\mathbb{Z}\Phi$ is torsion free and that q is a power of a good prime for Φ. We use the convention discussed in Remark 2.2 to vary q.

We recall that, with the above assumptions, the results of §2.3 say that the parameterization of the unipotent G^F-conjugacy classes does not depend on q. More specifically, there is a finite set E and finite groups A_e ($e \in E$), such that the unipotent G^F-conjugacy classes are parameterized by pairs (e, c) where $e \in E$ and c is a conjugacy class of A_e. This allows us to use the convention in Remark 2.6 to take a representative $u = u_{e,c}$ of the conjugacy class with label (e, c) that possibly changes as we vary q.

We can now state the main result of this section.

Theorem 3.10. *Fix the data $\Delta = (\Psi, \Pi, F_0, J)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. Assume that $X/\mathbb{Z}\Phi$ is torsion free and let q be a power of a good prime for Φ. Let G, F and P be the connected reductive group, Frobenius morphism and F-stable parabolic subgroup of G determined by Δ and q. Fix a label (e, c) of a unipotent G^F-conjugacy class and let $u \in G_{\mathrm{uni}}^F$ be a representative of this class.*

(i) *Suppose that G does not admit a simple component of type E_8. Then there exist $g_u(z), h_u(z) \in \mathbb{Z}[z]$ such that $|\mathcal{P}_u^F| = g_u(q)$ and $|(\mathcal{P}_u^0)^F| = h_u(q)$.*

14

(ii) *Suppose that G admits a simple component of type E_8. Then there exist $g_u^i(z), h_u^i(z) \in \mathbb{Z}[z]$ $(i = \pm 1)$ such that $|\mathcal{P}_u^F| = g_u^i(q)$ and $|(\mathcal{P}_u^0)^F| = h_u^i(q)$ when q is congruent to i modulo 3.*

Proof. First suppose that G does not have a simple component of type E_8. In this case, the discussion in §2.5 tells us that the Green functions $Q_{T_w}^G(u)$ are given by polynomials in q. Now it follows from Proposition 3.4(i) that there exists $g_u(z) \in \mathbb{Q}[z]$ such that $|\mathcal{P}_u^F| = g_u(q)$. That this polynomial has integer coefficients follows from Proposition 3.20 in the next subsection.

Observe that, as L^F is a finite reductive group, the factor $|L^F|_p$ in the formula for $|(\mathcal{P}_u^0)^F|$ in Proposition 3.4(ii) is the size of a Sylow p-subgroup of L^F. So by [6, Prop. 3.19], we have $|L^F|_p = q^N$, where N is the number of positive roots in the root system of L. Now it follows from Proposition 3.4(ii) that there exists $k_u(z) \in \mathbb{Q}[z]$ such that $|(\mathcal{P}_u^0)^F| = k_u(q)/q^N$. Since this holds for all applicable q, Lemma 2.12 tells us that $h_u(z) = k_u(z)/z^N$ is a polynomial in z. Again, the fact that $h_u(z)$ has integer coefficients follows from Proposition 3.20 in the next subsection.

In case G has a simple component of type E_8, the proposition is proved in the same way. In this case we use Remark 3.21 to ensure we have integer coefficients. $\square$

Remark 3.11. We note that in Theorem 3.10(ii) the need to consider polynomials depending on the congruence of q modulo 3 only arises in certain special cases, see Remark 2.10.

Remark 3.12. Remove the assumption that $X/\mathbb{Z}\Phi$ is torsion free, so that the centre of G is possibly disconnected. Let $\hat{G}$ be the semisimple adjoint group of the same type as G, and let $\phi : G \to \hat{G}$ be the natural map as in §2.3. Then it is straightforward to see that, for $u \in G_{\mathrm{uni}}^F$, we have $|\mathcal{P}_u^F| = |\hat{\mathcal{P}}_{\phi(u)}^F|$ and $|(\mathcal{P}_u^0)^F| = |(\hat{\mathcal{P}}_{\phi(u)}^0)^F|$. Therefore, with a certain formulation, a version of Theorem 3.10 holds when G has disconnected centre.

Using the `chevie` package in GAP3 ([7]) along with some code provided by M. Geck, we can calculate the polynomials $g_u(z)$ and $h_u(z)$ from Theorem 3.10. We illustrate this with some examples below.

Examples 3.13. (i). Suppose G is of type D_5. Let $u \in G_{\mathrm{uni}}^F$ lie in the minimal unipotent G-class. We note that the centralizer of u in G is connected, so the elements of G_{uni}^F in the minimal unipotent G-class form a single G^F-class. We have

$$|\mathcal{B}_u^F| = 5q^{13} + 24q^{12} + 60q^{11} + 106q^{10} + 145q^9 + 161q^8 + 150q^7 + 120q^6 + 85q^5 + 54q^4$$
$$+ 30q^3 + 14q^2 + 5q + 1$$

and for P a minimal parabolic subgroup we have

$$|\mathcal{P}_u^F| = q^{13} + 8q^{12} + 24q^{11} + 47q^{10} + 70q^9 + 83q^8 + 82q^7 + 69q^6 + 51q^5 + 34q^4$$
$$+ 20q^3 + 10q^2 + 4q + 1,$$
$$|(\mathcal{P}_u^0)^F| = 4q^{12} + 16q^{11} + 36q^{10} + 59q^9 + 75q^8 + 78q^7 + 68q^6 + 51q^5 + 34q^4 + 20q^3$$
$$+ 10q^2 + 4q + 1.$$

(ii). Now let G be of type G_2 and consider the unipotent G-class with Bala–Carter label $G_2(a_1)$. This is the subregular unipotent class in G. Let $u_1 \in G_{\mathrm{uni}}^F$ be a split element in this class. Then the component group of $C_G(u_1)$ is the symmetric group S_3 on 3 letters. Letting $u_2 \in (G \cdot u_1)^F$ be in the G^F-class corresponding to the conjugacy class of transpositions in

15

S_3 and $u_3 \in (G \cdot u_1)^F$ be in the G^F-class corresponding to the conjugacy class of 3-cycles. Then we have

$$|\mathcal{B}_{u_1}^F| = 4q + 1, \qquad |\mathcal{B}_{u_2}^F| = 2q + 1, \text{ and } \qquad |\mathcal{B}_{u_3}^F| = q + 1.$$

(iii). Finally we consider G of type F_4. Let P be the standard parabolic subgroup of G with Levi factor of type A_2 corresponding to the long roots of Π. For u the split representative in the conjugacy class with Bala–Carter label $F_4(a_3)$, we have

$$|(\mathcal{P}_u^0)^F| = 16q + 4.$$

For u split in the conjugacy class with Bala–Carter label $C_3(a_1)$, we have

$$|(\mathcal{P}_u^0)^F| = 4q^2 + 10q + 3.$$

We note that in these cases the constant term in the polynomial is not 1; in Remark 3.16(ii), we give an explanation for this.

Example 3.14. Let G be simple and split over $\mathbb{F}_q$, and let $u \in G_{\text{uni}}^F$ be a split subregular element of G. Let r be the rank of G. In [28, III 3.10 Thm. 2] R. Steinberg showed that $\mathcal{B}_u$ is a union of r projective lines with an intersection pattern determined by the Dynkin diagram of G; in this case $\mathcal{B}_u$ is called a *Dynkin curve*. It follows that $|\mathcal{B}_u^F| = rq + 1$, when G is simply laced, $|\mathcal{B}_u^F| = (2r - 1)q + 1$, $rq + 1$ in case G is of type B_r, C_r respectively, and $|\mathcal{B}_u^F| = (r + 2)q + 1$ for G of type G_2 and F_4.

3.3. **Geometric interpretation of the polynomials.** In this subsection we show that the polynomials $g_u(z)$ and $h_u(z)$ from Theorem 3.10 have integer coefficients. Further, in case G and u are split we are able to interpret the coefficients as Betti numbers of the relevant variety. For simplicity, we only consider the case where G does not have a simple component of type E_8; analogous results for the case where G is of type E_8 can be proved similarly, see Remark 3.21 for precise statements. We use the axiomatic setup from §2.2, so we fix the data $\Delta = (\Psi, \Pi, F_0, J)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. Then for any prime power q we have corresponding G, F and P. Throughout this subsection we only consider powers of good primes for Φ. Further, we assume that $X/\mathbb{Z}\Phi$ is torsion free, so that the centre of G is connected; we note that Remark 3.12 means that this latter assumption gives no essential loss in generality.

We begin by considering the case where F_0 is the identity; this corresponds to G being split over $\mathbb{F}_q$. Further, we begin by only considering unipotent G^F-conjugacy classes that contain a split element u (see §2.3), and we concentrate on the varieties $\mathcal{P}_u$ and polynomials $g_u(z)$.

With the above conditions we can consider $\mathcal{P}_u$ as a variety defined over $\mathbb{Z}$, so that for each prime power q the definition over $\mathbb{F}_q$ is obtained by changing base. In particular, if we fix a prime p, then $\mathcal{P}_u$ can be viewed as a variety defined over $\mathbb{F}_p$ and, for each power $q = p^s$ of p, the fixed points $\mathcal{P}_u^F$ of the corresponding Frobenius morphism are precisely the $\mathbb{F}_q$-rational points of $\mathcal{P}_u$ with respect to the $\mathbb{F}_p$-structure.

The discussion in the paragraph above, Lemma 2.13 and the purity of the variety $\mathcal{P}_u$ (as discussed in §2.4) imply the first part of Proposition 3.15 below; the second part holds for the same reasons.

Proposition 3.15. *Fix the data $\Delta = (\Psi, \Pi, F_0, J)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. Suppose Φ does not have an irreducible component of type E_8, the automorphism F_0 is the identity and*

16

$X/\mathbb{Z}\Phi$ is torsion free. Let q be a power of a good prime for Φ. Let G, F and P be the reductive group, Frobenius morphism and F-stable parabolic subgroup of G determined by Δ and q. Fix a split element $u \in G_{\mathrm{uni}}^F$.

(i) Let $g_u(z)$ be as in Theorem 3.10. Then

$$g_u(z) = \sum_{i=0}^{d_u} \dim H^{2i}(\mathcal{P}_u, \overline{\mathbb{Q}}_l) z^i,$$

where $d_u = \dim \mathcal{P}_u$.

(ii) Let $h_u(z)$ be as in Theorem 3.10. Then

$$h_u(z) = \sum_{i=0}^{d_u^0} \dim H^{2i}(\mathcal{P}_u^0, \overline{\mathbb{Q}}_l) z^i,$$

where $d_u^0 = \dim \mathcal{P}_u^0$.

Further, for i odd we have $H^i(\mathcal{P}_u, \overline{\mathbb{Q}}_l) = \{0\} = H^i(\mathcal{P}_u^0, \overline{\mathbb{Q}}_l)$ and all the eigenvalues of F on $H^{2i}(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$ and $H^{2i}(\mathcal{P}_u^0, \overline{\mathbb{Q}}_l)$ are q^i for all i. In particular, the Euler characteristics of $\mathcal{P}_u$ and $\mathcal{P}_u^0$ are given by $g_u(1)$ and $h_u(1)$, respectively.

The special case $P = B$ in Proposition 3.15 is well-known, e.g. see [20, Cor. 6.4].

Remarks 3.16. (i). We note that the values $\dim H^i(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$ and $\dim H^i(\mathcal{P}_u^0, \overline{\mathbb{Q}}_l)$ are the *Betti numbers* of the underlying varieties $\mathcal{P}_u$ and $\mathcal{P}_u^0$, respectively. Thus, Proposition 3.4 gives an effective way to calculate these invariants. For example, consider G of type D_5 and u in the minimal unipotent G-conjugacy class and P a minimal parabolic subgroup. The expressions given in Example 3.13 tell us, for instance, that $\dim H^{10}(\mathcal{P}_u, \overline{\mathbb{Q}}_l) = 85$ and $\dim H^{20}(\mathcal{P}_u^0, \overline{\mathbb{Q}}_l) = 36$.

(ii). It follows from [29, Cor. 2.4] that $\mathcal{P}_u$ is connected. Thus the constant term of $g_u(z)$ is 1. In contrast, it is not always the case that $\mathcal{P}_u^0$ is connected, this follows from the values of $h_u(z)$ for G of type F_4 given in Example 3.13; another example is given in [22, II 11.8(b)].

Remark 3.17. Let P and Q be associated F-stable parabolic subgroups of G and let $\mathcal{P}$ and $\mathcal{Q}$ be the corresponding generalized flag varieties. Then it follows from Corollary 3.5 and Proposition 3.15 that for $u \in G_{\mathrm{uni}}^F$ split, the Betti numbers of $\mathcal{P}_u$ and $\mathcal{Q}_u$ (respectively $\mathcal{P}_u^0$ and $\mathcal{Q}_u^0$) coincide. We note that this has been observed by Borho–MacPherson ([3, Cor. 3.7]) and that it holds without the assumption that G and u are split. In particular, $\dim H^{2d_u}(\mathcal{P}_u, \overline{\mathbb{Q}}_l) = \dim H^{2d_u}(\mathcal{Q}_u, \overline{\mathbb{Q}}_l)$ implies that $\mathcal{P}_u$ and $\mathcal{Q}_u$ have the same number of irreducible components of maximal dimension. We note that it is not always the case that $\mathcal{P}_u$ and $\mathcal{Q}_u$ have the same number of irreducible components in lower dimensions (unlike $\mathcal{B}_u$ which is equidimensional, [22, II Prop. 1.12]); see [22, II 11.5] for an example in case $G = \mathrm{GL}_4$.

Analogous statements hold if we replace $\mathcal{P}_u$ and $\mathcal{Q}_u$ by $\mathcal{P}_u^0$ and $\mathcal{Q}_u^0$; see [22, II 11.6] for an explicit example where the number of irreducible components differs. We note however that for $G = \mathrm{GL}_n$, the varieties $\mathcal{P}_u^0$ are equidimensional, see the final corollary in [21]; also see [22, II Prop. 5.15].

Remark 3.18. Next we discuss some special cases where there is an alternative way to see that $|\mathcal{P}_u^F|$ is a polynomial in q with coefficients independent of q. Let G and $u \in G_{\mathrm{uni}}^F$ be split.

Suppose that $\mathcal{P}_u$ admits a stratification into a finite union of locally closed subvarieties, so that the decomposition does not depend on q and each stratum is isomorphic to some affine space and is defined over $\mathbb{F}_q$; such a decomposition is called a *paving by affine spaces*. It then follows that $|\mathcal{P}_u^F|$ is a polynomial in q. Further, the coefficient of q^i in this polynomial is the number of strata isomorphic to affine i-space $\mathbb{A}^i$; by Proposition 3.15 this coefficient is also the $(2i)$th Betti number of $\mathcal{P}_u$. Below we give some examples when such a stratification is known to exist.

(i). In case $u = 1$, the Bruhat decomposition of G implies that there is a paving of $\mathcal{B}_1 = \mathcal{B}$ by affine spaces, and one deduces that $\dim H^{2i}(\mathcal{B}, \overline{\mathbb{Q}}_l)$ is the number of elements of W of length i. Likewise, the Bruhat decomposition can be used to obtain a stratification of $\mathcal{P}$ and to interpret the $(2i)$th Betti number of $\mathcal{P}$ as the number of elements of length i in the set of distinguished coset representatives in W/W_L.

(ii) Suppose G is simple. It is known in all cases apart from E_7 and E_8 that $\mathcal{B}_u$ admits such a desired paving by affine spaces for any $u \in G_{\mathrm{uni}}$, see [5, Thm. 3.9], [22, II Prop. 5.9], and [23, Thm. 2]. See also [10, Ch. 11]. In case u is in the subregular class of G_{uni}, $\mathcal{B}_u$ is a Dynkin curve (as mentioned in Example 3.14). Therefore, $\mathcal{B}_u$ is the disjoint union of affine lines and points with no restriction on the type of G. Also, if u is a root element in G_{uni}, then $\mathcal{B}_u$ admits an affine paving, irrespective of the type of G, see [25, Prop. 7.11].

(iii). Now suppose $G = \mathrm{GL}_n$ and P is an F-stable parabolic subgroup of G with associated generalized flag variety $\mathcal{P}$. In [19], N. Shimomura showed that $\mathcal{P}_u$ admits a paving by affine spaces for any P and any u

In view of the special situations discussed in Remark 3.18 it is natural to ask whether in general there are suitable decompositions of $\mathcal{P}_u$ and $\mathcal{P}_u^0$ into finite sets of locally closed subvarieties each of which is isomorphic to some affine space. In particular, this is consistent with the vanishing of the odd l-adic cohomology of $\mathcal{P}_u$ and $\mathcal{P}_u^0$, as shown in Proposition 3.15.

Now we consider the situation when u is not split (still assuming that G is split). So we fix a label (e, c) of a unipotent G^F-conjugacy class and let u be a representative of this conjugacy class; we use Remark 2.6 to vary q. We recall that u is split if the permutation action of F on the irreducible components of $\mathcal{B}_u$ is trivial.

Since there are finitely many irreducible components of $\mathcal{B}_u$, there is a minimal positive integer s such that the action of F^s on the set of irreducible components of $\mathcal{B}_u$ is trivial. (We note that s is the order of an element of the conjugacy class c in the group A_e, but as we do not require this fact we do not give a proof of it.) Therefore, considered as an element of G^{F^s} we have that u is split. Hence, by Proposition 3.15 above, the l-adic cohomology groups vanish in odd degrees, and the eigenvalues of F^s on the l-adic cohomology groups $H^{2i}(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$ are all q^{is} for $i = 0, \ldots, d_u$. Therefore, the eigenvalues of F on $H^{2i}(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$ are of the form $\zeta^j q^i$, where ζ is a primitive sth root of unity and $j = 0, \ldots, s-1$. Let $n_{i,j}$ be the number of times $\zeta^j q^i$ ($j = 0, \ldots, s-1$) occurs as an eigenvalue of F on $H^i(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$. Using the Grothendieck trace formula we get

$$(3.19) \qquad |\mathcal{P}_u^F| = \sum_{i=0}^{d_u} \sum_{j=0}^{s-1} n_{i,j} \zeta^j q^i.$$

18

Since (3.19) holds for all q and $|\mathcal{P}_u^F| = g_u(q)$, we see that the $n_{i,j}$ do not depend on q. It follows that the coefficients of $g_u(z)$ are algebraic integers. Since these coefficients are also rational numbers, we must have $g_u(z) \in \mathbb{Z}[z]$.

Next we consider the case where we no longer assume that F_0 is the identity, i.e. that G is not split over $\mathbb{F}_q$. The automorphism F_0 is of finite order, say r. Then F^r is a Frobenius morphism on G corresponding to a split $\mathbb{F}_{q^r}$-structure. The discussion in the previous paragraph then tells us that the eigenvalues of F^r on $H^{2i}(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$ are of the form $\zeta^j q^{ir}$, where ζ is some root of unity. It follows that the eigenvalues of F on $H^{2i}(\mathcal{P}_u, \overline{\mathbb{Q}}_l)$ are of the form $\xi^j q^i$, where ξ is some root of unity. Now an analogue of (3.19) holds and we can deduce as before that $g_u(z) \in \mathbb{Z}[z]$.

Proposition 3.20 completes the proof of Theorem 3.10. We have proved the statement about $g_u(z)$ and the assertion about $h_u(z)$ is proved in the same way.

Proposition 3.20. *Fix the data* $\Delta = (\Psi, \Pi, F_0, J)$, *where* $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. *Assume that* Φ *does not have a simple component of type* E_8 *and* $X/\mathbb{Z}\Phi$ *is torsion free. Let* q *be a power of a good prime for* Φ. *Let* G, F *and* P *be the connected reductive group, Frobenius morphism and* F-*stable parabolic subgroup of* G *determined by* Δ *and* q. *Fix a label* (e, c) *of a unipotent* G^F-*conjugacy class and let* $u \in G_{\mathrm{uni}}^F$ *be a representative of this class.*

Let $g_u(z), h_u(z)$ *be as in Theorem 3.10. Then we have* $g_u(z), h_u(z) \in \mathbb{Z}[z]$.

Remark 3.21. Suppose G has a simple component of type E_8. Then for $u \in G_{\mathrm{uni}}^F$ split, the formulas in Proposition 3.15 hold for $g_u^1(z)$ and $h_u^1(z)$. Further, the analogue of Proposition 3.20 holds, i.e. that $g_u^i(z), h_u^i(z) \in \mathbb{Z}[z]$ $(i = \pm 1)$. As mentioned in Remark 3.11, we only actually need to consider two polynomials depending on the congruence of q modulo 3 in certain special cases.

4. Unipotent conjugacy in finite groups of Lie type

In this section we apply the results of the previous sections in order to prove our generalization (Theorem 4.5) of the main theorem in Alperin's note [1].

4.1. A counting argument for finite groups.

For the first part of this subsection let G be a finite group and let H be a subgroup of G. In Lemma 4.1 below we give a formula for the number of H-conjugacy classes in G. This lemma was proved, for a particular case, in [1], and the proof applies generally without change; we include the proof for the reader's convenience. Before stating the lemma we need to introduce some notation.

For $x \in G$ we define

$$f_H^G(x) = |\{ {}^g H \mid x \in {}^g H, g \in G \}|$$

for the number of conjugates of H in G containing x. By $k(H, G)$ we denote the number of H-conjugacy classes in G and we let $\mathcal{R} = \mathcal{R}(G, H)$ be a set of representatives of the distinct G-conjugacy classes that intersect H.

Lemma 4.1. *The number of H-conjugacy classes in G is given by*

$$k(H, G) = \frac{|N_G(H)|}{|H|} \sum_{x \in \mathcal{R}} f_H^G(x).$$

Proof. Counting the set of pairs $\{(y, {}^gH) \mid y \in G \cdot x, g \in G, y \in {}^gH\}$ in two different ways, we obtain $|G : N_G(H)| \cdot |G \cdot x \cap H| = |G \cdot x| \cdot f_H^G(x)$. It follows that

$$|G \cdot x \cap H| = \frac{|G \cdot x|}{|G : N_G(H)|} \cdot f_H^G(x).$$

Now Burnside's counting formula gives

$$k(H, G) = \frac{1}{|H|} \sum_{x \in H} |C_G(x)| = \frac{1}{|H|} \sum_{x \in \mathcal{R}} |G \cdot x \cap H| \cdot |C_G(x)|.$$

Thus it follows that

$$k(H, G) = \frac{1}{|H|} \sum_{x \in \mathcal{R}} |G \cdot x| \cdot \frac{|N_G(H)|}{|G|} \cdot \frac{|G|}{|G \cdot x|} \cdot f_H^G(x) = \frac{|N_G(H)|}{|H|} \sum_{x \in \mathcal{R}} f_H^G(x),$$

as claimed. $\qquad\square$

Now suppose G is a connected reductive group defined over $\mathbb{F}_q$ with corresponding Frobenius morphism F of G. Let H be a closed F-stable subgroup of G. In this situation we write f_H^G rather than $f_{H^F}^{G^F}$ to shorten notation; we note that this notation has already been used in §3.1. We can apply Lemma 4.1 in the case "$G = G^F$" and "$H = H^F$" and we obtain the formula

$$k(H^F, G^F) = \frac{|N_G(H^F)|}{|H^F|} \sum_{x \in \mathcal{R}} f_H^G(x),$$

where $\mathcal{R} = \mathcal{R}(G^F, H^F)$ is a set of representatives of all G^F-conjugacy classes that intersect H^F.

Lastly in this subsection, we remark on a connection between the functions f_H^G and so called fixed point ratios for finite group actions; for the importance of the latter see for instance [13] and the references therein.

Remark 4.2. Let G be a finite group and let H be a subgroup. Consider the transitive action of G on the cosets G/H. For x in G, the *fixed point ratio* of x in this action is given by

$$\mathrm{fpr}(x, G/H) = \frac{\mathrm{fix}_{G/H}(x)}{|G/H|} = \frac{|G \cdot x \cap H|}{|G \cdot x|},$$

where $\mathrm{fix}_{G/H}(x)$ denotes the number of fixed points of x on G/H, see [13]. In particular, by the counting argument in the proof of Lemma 4.1 we get

$$\mathrm{fpr}(x, G/H) = \frac{|N_G(H)|}{|G|} f_H^G(x).$$

4.2. **Unipotent conjugacy in Finite Groups of Lie Type.** For the start of this section we do not require the axiomatic setup of §2.2, but we do use the notation of §2.1. So G is a connected reductive algebraic group defined over $\mathbb{F}_q$ with corresponding Frobenius morphism F. The parabolic subgroup P of G is F-stable with unipotent radical U. We have a maximally split maximal torus T of G and L is the unique Levi subgroup of P containing T.

The next proposition is proved using Lemmas 3.3 and 4.1.

Proposition 4.3. *The number of U^F-conjugacy classes in G^F is given by*

$$k(U^F, G^F) = |L^F|_{p'} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} \sum_{u \in \mathcal{R}} Q^G_{T_w}(u),$$

where $\mathcal{R} = \mathcal{R}(G^F, U^F)$ is a set of representatives of the conjugacy classes of G^F that intersect U^F.

Proof. We have $N_{G^F}(U^F) = P^F$ and therefore $|N_{G^F}(U^F)|/|U^F| = |L^F|$. Thus it follows from Lemmas 3.3 and 4.1 that

$$k(U^F, G^F) = |L^F| \sum_{u \in \mathcal{R}} f^G_U(u)$$

(4.4)
$$= |L^F| \sum_{u \in \mathcal{R}} \frac{1}{|L^F|_p} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} Q^G_{T_w}(u)$$

$$= |L^F|_{p'} \cdot \frac{1}{|W_L|} \sum_{w \in W_L} (-1)^{l(w)} \sum_{u \in \mathcal{R}} Q^G_{T_w}(u),$$

as claimed. $\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad$ □

For the remainder of this subsection we use the axiomatic setup of §2.2. We fix the data $\Delta = (\Psi, \Pi, F_0, J)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. Then for each prime power q we have a connected reductive algebraic group G defined over $\mathbb{F}_q$ with Frobenius morphism F and we have the F-stable parabolic subgroup $P = P_J$ of G. We denote the unipotent radical of P by U and we write L for the unique Levi subgroup of P containing T. In order to state the results in this subsection we use the convention discussed in Remark 2.2 to vary q.

We now state and prove the principal result of this section; it generalizes the main theorem of [1], which is the special case $G = \mathrm{GL}_n$ and $P = B$ of Theorem 4.5.

Theorem 4.5. *Fix the data $\Delta = (\Psi, \Pi, F_0, J)$, where $\Psi = (X, \Phi, \check{X}, \check{\Phi})$. For a prime power q, let G, F and P be the connected reductive group, Frobenius morphism and F-stable parabolic subgroup of G determined by Δ and let $U = R_u(P)$. Assume that $X/\mathbb{Z}\Phi$ is torsion free and that q is a power of a good prime for Φ.*

  (i) *Suppose that G does not have a simple component of type E_8. Then there exists $m(z) \in \mathbb{Z}[z]$ such that $k(U^F, G^F) = m(q)$.*
  (ii) *Suppose that G has a simple component of type E_8. Then there exist $m^i(z) \in \mathbb{Z}[z]$ ($i = \pm 1$), such that $k(U^F, G^F) = m^i(q)$, when q is congruent to i modulo 3.*

Proof. The first equality in (4.4) says that

$$k(U^F, G^F) = |L^F| \sum_{u \in \mathcal{R}} f^G_U(u).$$

Since L^F is a finite reductive group, the factor $|L^F|$ is a polynomial in q, e.g., see [4, p. 75]. By Lemma 3.1(ii) and Theorem 3.10 each of the summands $f^G_U(u)$ is a polynomial in q. With the assumption that $X/\mathbb{Z}\Phi$ is torsion free, it follows from Proposition 2.5 that the set $\mathcal{R} = \mathcal{R}(G^F, U^F)$ is independent of q, where we use the convention of Remark 2.6. $\qquad$ □

Remark 4.6. By Remark 2.10, if G has a simple component of type E_8 and P is an F-stable parabolic subgroup of G, then the polynomial $k(U^F, G^F)$ in q in Theorem 4.5(ii) only depends

on the residue class of q modulo 3 in case U meets the unipotent class with Bala–Carter label $E_8(b_6)$. For G simple of type E_8, it is straightforward to calculate the parabolic subgroups of G for which this occurs; for example this class does not meet the unipotent radical of any of the maximal parabolic subgroups of G.

It was already remarked that the formula in Lemma 3.3 for $f_U^G(u)$ does not depend on the choice of an F-stable parabolic subgroup P of G containing L as a Levi subgroup. This enabled us to deduce Corollary 3.5. Similarly, we can deduce the following corollary from Theorem 4.5.

Corollary 4.7. *Assume as in Theorem 4.5. Let P and Q be associated F-stable parabolic subgroups of G with unipotent radicals U and V respectively. Then*

$$k(U^F, G^F) = k(V^F, G^F) = m(q),$$

where $m(z) \in \mathbb{Z}[z]$ is as in Theorem 4.5.

Proof. We note that two associated parabolic subgroups of G have the same Richardson class (see [11]). Consequently, the sets of unipotent classes of G meeting the unipotent radicals of two associated parabolic subgroups coincide. Now it follows immediately from the expression for $k(U^F, G^F)$ given in Proposition 4.3 that $k(U^F, G^F) = k(V^F, G^F)$ and the final equality follows from Theorem 4.5. (If G admits a simple component of type E_8, then there are two polynomials depending on the congruence class of q modulo 3.) $\square$

Remark 4.8. Assume as in Theorem 4.5. The *commuting variety of U and G* is the closed subvariety of $U \times G$ defined by

$$\mathcal{C}(U, G) = \{(u, g) \in U \times G \mid ug = gu\}.$$

Since U is F-stable, F acts on $\mathcal{C}(U, G)$ and we can consider the F-fixed points and we have $\mathcal{C}(U, G)^F = \mathcal{C}(U^F, G^F)$. The Burnside counting formula tells us that

$$|\mathcal{C}(U, G)^F| = q^{\dim U} k(U^F, G^F) = q^{\dim U} m(q),$$

where $m(z) \in \mathbb{Z}[z]$ is as in Theorem 4.5. In particular, $|\mathcal{C}(U, G)^F|$ is given by a polynomial in q with integer coefficients independent of q. (If G admits a simple component of type E_8, there are two polynomials depending on the congruence class of q modulo 3.) We note that the coefficients of the polynomial $m(z)$ can be negative (see the Examples 4.9). This means that the variety $\mathcal{C}(U, G)$ is not, in general, pure and therefore we cannot interpret the coefficients as Betti numbers as in Lemma 2.13. We do note, however, that the Euler characteristic of $\mathcal{C}(U, G)$ is given by $m(1)$, which is always equal to 0 by the formula in Proposition 4.3.

Using the `chevie` package in GAP3 ([7]) along with some code provided by M. Geck, we are able to explicitly calculate the polynomials $m(z)$ in Theorem 4.5. We illustrate this with some examples below.

Examples 4.9. (i). In Table 1 below we give the polynomials for $k(U^F, G^F)$ in case $G = \mathrm{PGL}_n$ and $P = B$ for $n = 2, \ldots, 10$. In this case we can take $U = \mathrm{U}_n$ to be the group of upper unitriangular matrices. We note that it follows from the first equality in (4.4) that $k(\mathrm{U}_n(q), \mathrm{GL}_n(q)) = (q-1)k(\mathrm{U}_n(q), \mathrm{PGL}_n(q))$, because $f_{\mathrm{U}_n}^{\mathrm{GL}_n}(u) = f_{\mathrm{U}_n}^{\mathrm{PGL}_n}(u)$ for any $u \in \mathrm{U}_n$.

n	$k(\mathrm{U}_n(q), \mathrm{PGL}_n(q))$
2	$q^2 + q - 2$
3	$q^5 + q^3 - 3q^2 - 2q + 3$
4	$q^9 - q^7 + 2q^6 - 3q^5 - 2q^4 - 4q^3 + 9q^2 + 3q - 5$
5	$q^{14} - q^{12} - q^{11} + 3q^{10} - 5q^9 + 2q^8 - 9q^6 + 11q^5 + 10q^4 - q^3 - 13q^2 - 4q + 7$
6	$q^{20} - q^{18} - q^{17} - q^{16} + 5q^{15} - 6q^{14} - 3q^{13} + 12q^{12} + 3q^{11} - 40q^{10} + 44q^9 - 7q^8 + 5q^7 + 3q^6 - 5q^5 - 38q^4 + 11q^3 + 24q^2 + 5q - 11$
7	$q^{27} - q^{25} - q^{24} - q^{23} + 6q^{21} - 6q^{20} - 4q^{19} + 3q^{18} + 16q^{17} + 2q^{16} - 45q^{15} + 9q^{14} + 65q^{13} - 36q^{12} - 47q^{11} + 118q^{10} - 130q^9 + 80q^8 - 85q^7 + 25q^6 + 34q^5 + 46q^4 - 27q^3 - 31q^2 - 6q + 15$

9	$q^{44} - q^{42} - q^{41} - q^{40} + q^{37} + 9q^{36} - 8q^{35} - 6q^{34} + 3q^{33} + q^{32} + 8q^{31} + 25q^{30} - 2q^{29} - 113q^{28} + 49q^{27} + 107q^{26} - 60q^{25} + 81q^{24} - 326q^{23} + 97q^{22} + 702q^{21} - 603q^{20} - 446q^{19} + 337q^{18} + 760q^{17} - 869q^{16} + 491q^{15} - 957q^{14} + 1063q^{13} - 142q^{12} + 123q^{11} - 939q^{10} + 1130q^9 - 622q^8 - 255q^7 + 429q^6 - 60q^5 + 124q^4 - 92q^3 - 60q^2 - 8q + 30$
10	$q^{54} - q^{52} - q^{51} - q^{50} + q^{47} + q^{46} + 10q^{45} - 9q^{44} - 7q^{43} + 2q^{42} + q^{41} + 9q^{40} - 3q^{39} + 41q^{38} - 12q^{37} - 144q^{36} + 61q^{35} + 77q^{34} + 89q^{33} - 90q^{32} - 5q^{31} - 189q^{30} - 109q^{29} + 561q^{28} + 256q^{27} - 746q^{26} - 50q^{25} - 1070q^{24} + 3249q^{23} - 682q^{22} - 4884q^{21} + 3467q^{20} + 5522q^{19} - 8703q^{18} + 757q^{17} + 5424q^{16} - 1423q^{15} - 1450q^{14} - 4812q^{13} + 10000q^{12} - 6872q^{11} + 726q^{10} + 1638q^9 - 555q^8 + 509q^7 - 858q^6 + 307q^5 - 222q^4 + 137q^3 + 85q^2 + 9q - 42$

TABLE 1. $k(\mathrm{U}_n(q), \mathrm{PGL}_n(q))$

(ii). Now suppose that G is split of type E_6. For $P = B$, we have

$$
\begin{aligned}
m(q) = {} & q^{42} - q^{40} - q^{37} - q^{36} + q^{35} - q^{33} + q^{32} + 8q^{31} - 2q^{30} - 6q^{29} - 2q^{28} - 6q^{27} + 18q^{26} \\
& - 24q^{25} - 6q^{24} + 34q^{23} + 90q^{21} - 122q^{20} - 59q^{19} - 69q^{18} + 101q^{17} + 304q^{16} - 265q^{15} \\
& + 234q^{14} + 48q^{13} - 1891q^{12} + 2658q^{11} - 220q^{10} - 1794q^9 + 818q^8 + 527q^7 - 521q^6 \\
& + 213q^5 + 11q^4 - 78q^3 - 17q^2 - 6q + 25,
\end{aligned}
$$

and if P is a minimal parabolic subgroup of G, then $k(U^F, G^F)$ is given by

$$
\begin{aligned}
m(q) = {} & q^{43} - q^{41} - q^{38} - q^{37} + q^{36} - q^{34} + q^{33} + 7q^{32} - q^{31} - 5q^{30} - 2q^{29} - 6q^{28} + 12q^{27} \\
& - 13q^{26} - 9q^{25} + 23q^{24} + 7q^{23} + 65q^{22} - 61q^{21} - 81q^{20} - 53q^{19} + 47q^{18} + 231q^{17} \\
& - 78q^{16} + 42q^{15} + 79q^{14} - 987q^{13} + 748q^{12} + 931q^{11} - 1191q^{10} - 129q^9 + 563q^8 \\
& - 39q^7 - 117q^6 + 74q^5 - 37q^4 - 40q^3 - 3q^2 + 24q.
\end{aligned}
$$

(iii). Now consider the case G is of type E_6 with twisted definition over $\mathbb{F}_q$, i.e. $G^F = {}^2E_6(q)$. Then for a Borel subgroup of G we have

$$
\begin{aligned}
m(q) = {} & q^{42} - 8q^{41} + 31q^{40} - 80q^{39} + 160q^{38} - 273q^{37} + 423q^{36} - 615q^{35} + 848q^{34} - 1113q^{33} \\
& + 1401q^{32} - 1710q^{31} + 2039q^{30} - 2376q^{29} + 2699q^{28} - 2992q^{27} + 3258q^{26} - 3521q^{25} \\
& + 3821q^{24} - 4201q^{23} + 4698q^{22} - 5347q^{21} + 6155q^{20} - 7035q^{19} + 7831q^{18} - 8471q^{17} \\
& + 9005q^{16} - 9454q^{15} + 9764q^{14} - 9947q^{13} + 10114q^{12} - 10268q^{11} + 10141q^{10} - 9392q^{9} \\
& + 7989q^{8} - 6252q^{7} + 4526q^{6} - 2998q^{5} + 1770q^{4} - 893q^{3} + 354q^{2} - 94q + 12.
\end{aligned}
$$

For a minimal parabolic subgroup of G, we have

$$
\begin{aligned}
m(q) = {} & q^{43} - 6q^{42} + 17q^{41} - 32q^{40} + 48q^{39} - 65q^{38} + 85q^{37} - 107q^{36} + 126q^{35} - 139q^{34} \\
& + 149q^{33} - 160q^{32} + 169q^{31} - 168q^{30} + 155q^{29} - 138q^{28} + 127q^{27} - 130q^{26} + 154q^{25} \\
& - 200q^{24} + 264q^{23} - 341q^{22} + 409q^{21} - 420q^{20} + 357q^{19} - 280q^{18} + 233q^{17} - 171q^{16} \\
& + 71q^{15} - 4q^{14} + 18q^{13} - 29q^{12} - 107q^{11} + 410q^{10} - 718q^{9} + 863q^{8} - 834q^{7} + 706q^{6} \\
& - 531q^{5} + 346q^{4} - 182q^{3} + 65q^{2} - 11q.
\end{aligned}
$$

In case G has disconnected centre, the parameterization of the unipotent G^F-conjugacy classes depends on q, as discussed at the end of §2.3. We also mentioned that this dependence is only up to congruences on q. From this discussion, Theorem 4.5 and Remark 3.12 it follows that $k(U^F, G^F)$ is given by polynomials up to congruences on q. We illustrate this in the following example.

Example 4.10. Let $G = \mathrm{SL}_3$. In this case, we have three F-stable unipotent G-conjugacy classes, as mentioned in Example 2.7. The class corresponding to the partition $(1, 1, 1)$ is $\{1\}$, which forms a single G^F-conjugacy class; one can also show that the F-stable class corresponding to the partition $(2, 1)$ is a single G^F-class. As discussed in Example 2.7 the regular class splits into three G^F-classes if $q \equiv 1 \mod 3$ and forms a single G^F-class if $q \equiv 0, -1 \mod 3$. We consider the case when $P = B$ is a Borel subgroup of G. One can calculate the value $f_U^G(u)$ to be 1, $2q + 1$, $(q^2 + q + 1)(q + 1)$ for u in the class labeled (3), $(2, 1)$, $(1, 1, 1)$, respectively. Using the formula given in the first equation in (4.4), we obtain

$$
\begin{aligned}
k(U^F, G^F) &= (q-1)^2 (3 + 2q + 1 + (q^2 + q + 1)(q + 1)) \\
&= q^5 + q^3 - q^2 - 6q + 5,
\end{aligned}
$$

for $q \equiv 1 \mod 3$; and

$$
\begin{aligned}
k(U^F, G^F) &= (q-1)^2 (1 + 2q + 1 + (q^2 + q + 1)(q + 1)) \\
&= q^5 + q^3 - 3q^2 - 2q + 3,
\end{aligned}
$$

for $q \equiv 0, -1 \mod 3$. So $k(U^F, G^F)$ is given by two polynomials depending on congruences of q modulo 3.

The formula in Proposition 4.3 and Remark 2.11 suggest that the values of $k(U^F, G^F)$ differ for good and bad primes. Below we give an example where this does occur.

Example 4.11. Consider G of type C_2 and $P = B$ a Borel subgroup of G. If q is the power of an odd prime, then we have

$$k(U^F, G^F) = q^6 + 4q^3 - 8q^2 - 2q + 5$$

while if q is a power of 2, then we get

$$k(U^F, G^F) = q^6 + q^4 + 2q^3 - 6q^2 - 4q + 6.$$

We are grateful to M. Geck for the computation of these polynomials.

Remark 4.12. Let P be an F-stable parabolic subgroup of G. Using Lemma 4.1 and the fact that $P = N_G(P)$ we obtain

$$(4.13) \qquad\qquad k(P^F, G^F) = \sum_{x \in \mathcal{R}} f_P^G(x),$$

where $\mathcal{R} = \mathcal{R}(P^F, G^F)$ is a set of representatives of the conjugacy classes of G^F that intersect P^F. From the proof of Lemma 3.2 we get an expression of $f_P^G(x)$ as a sum of Deligne–Lusztig generalized characters, but this is a linear combination of Green functions only in case x is unipotent. Further, the set $\mathcal{R}$ over which the sum is taken depends heavily on q, so it is non-trivial to determine whether $k(P^F, G^F)$ is given by a polynomial in q.

In [1] it is shown, using an expression as in (4.13), that $k(B^F, G^F)$ is given by a polynomial in q, in case $G = \mathrm{GL}_n$. The proof of this depends on partitioning the set $\mathcal{R}(B^F, G^F)$ into a finite union $\mathcal{R}(B^F, G^F) = \mathcal{R}_1 \cup \cdots \cup \mathcal{R}_t$ independent of q such that: $f_B^G(x) = f_B^G(y)$ if $x, y \in \mathcal{R}_i$; and $|\mathcal{R}_i|$ is given by a polynomial in q. That $f_B^G(x)$ is given by a polynomial in q for $x \in \mathcal{R}_i$, is deduced from the fact that $f_{C_B(s)}^{C_G(s)}(u)$ is a polynomial in q, where $x = su$ is the Jordan decomposition of x.

It is possible to give an analogous decomposition $\mathcal{R}(P^F, G^F) = \mathcal{R}_1 \cup \cdots \cup \mathcal{R}_t$ for arbitrary connected reductive G with parabolic subgroup P. Further, it is possible to reduce the calculation of $f_P^G(x)$ to that of $f_Q^H(u)$ for certain pseudo Levi subgroups $H = C_G(s)^\circ$ of G and parabolic subgroups Q of H, where $x = su$ is the Jordan decomposition of x. However, this reduction will involve considering such H with disconnected centre, so one can only really hope to prove that $f_P^G(x)$ is given by polynomials in q up to congruences on q; even in case $P = B$ is a Borel subgroup of G.

We believe that $f_P^G(x)$ is indeed given by polynomials up to congruences on q and hope to address this in the future.

APPENDIX A. THE GL_n CASE

In this appendix, we give an elementary proof of the existence of the polynomial $h_u(z)$ in Theorem 3.10 for the case $G = \mathrm{GL}_n$ with standard definition over $\mathbb{F}_q$. In this case existence of $h_u(z)$ follows from the theory of Jordan normal forms, so one obtains an elementary proof of Theorem 4.5. The proof is purely combinatorial, beginning with two counting lemmas.

Let V be an n-dimensional vector space over $\mathbb{F}_q$ and let W be an m-dimensional subspace of V. Let $l \in \mathbb{Z}_{\geq 0}$ and define

$$\mathcal{S}(V, W, l) = \{U \subseteq V \mid \dim U = l, \ U \cap W = \{0\}\}.$$

We note that the order of $\mathcal{S}(V, W, l)$ depends only on n, m and l (and not on the choice of V and W). As we let q vary, the order of $\mathcal{S}(V, W, l)$ defines a function of q, which we denote by $s(n, m, l)(q)$.

The following lemma is proved using an easy counting argument.

Lemma A.1. *We have*

$$s(n, m, l)(q) = \prod_{i=0}^{l-1} \frac{q^n - (q^m + q^i - 1)}{q^i - q^{i-1}}.$$

In particular, $s(n, m, l)(q)$ is a polynomial in q.

Proof. Suppose we have chosen subspace U' of V with $\dim U' = l-1$ and $U' \cap W = \{0\}$. Then the number of ways of extending U' to $U \in \mathcal{S}(V, W, l)$ is $(q^n - (q^m + q^{l-1} - 1))/(q^{l-1} - q^{l-2})$. The formula for $s(n, m, l)(q)$ now follows by induction. We have that $s(n, m, l)(q)$ is a polynomial in q by Lemma 2.12 $\qquad\qquad\square$

We recall that a flag F in V is a sequence of subspaces $\{0\} = V_0 \subseteq \ldots \subseteq V_r = V$; in this appendix we only consider proper flags so $V_i \neq V_{i+1}$ for all i. The dimension vector of F is the r-tuple $d = (d_1, \ldots, d_r) \in \mathbb{Z}_{\geq 1}^r$, where $d_i = \dim V_i$. Fix a flag F in V with dimension vector d and let $e = (e_1, \ldots, e_r) \in \mathbb{Z}_{\geq 0}^r$ be an r-tuple with $e_i \leq d_i$ and $e_i \leq e_{i+1}$ for each i. We define $\mathcal{T}(F, e)$ to be the set of subspaces U of V such that $\dim(U \cap V_i) = e_i$ for each i. It is clear that the order of $\mathcal{T}(F, e)$ depends only on the vectors d and e and as q varies, it defines a function $t(d, e)(q)$ of q. We prove the following lemma by induction using Lemma A.1.

Lemma A.2. $t(d, e)(q)$ *is a polynomial in q.*

Proof. We work by induction on r. The case $r = 0$ is trivial. Therefore, we may assume that the number of ways of choosing $U' \subseteq V_{r-1}$ such that $\dim(U' \cap V_i) = e_i$ for $i = 1, \ldots, r-1$ is given by a polynomial in q. Given such U', the number of ways of extending U' to U such that $U \cap V_{r-1} = U'$ and $\dim(U \cap V_r) = e_r$ is the number of subspaces of V_r/U' of dimension $e_r - e_{r-1}$ that intersect V_{r-1}/U' trivially. The induction is now completed using Lemma A.1. $\qquad\qquad\square$

We retain the notation that V is an n-dimensional vector space over $\mathbb{F}_q$ and we define $G = \mathrm{GL}(V)$. For a fixed dimension vector $d = (d_1, \ldots, d_r)$ ($d_r = n$, $d_{i-1} < d_i$), we define $\mathrm{Flag}(V, d)$ to be the set of all flags of V with dimension vector d.

In this appendix we denote a partition π of n by the n-tuple $(\pi_1, \ldots, \pi_n)$ of non-negative integers such that $\sum_{i=1}^n i\pi_i = n$. We denote by $\Pi(n)$ the set of all partitions of n. We recall that the unipotent conjugacy classes in G are parameterized by the partitions of n (by the theory of Jordan normal forms). Given a partition π of n, let $x_\pi \in G$ be a representative of the conjugacy class corresponding to π; we write $y_\pi = x_\pi - 1$. For any unipotent element $x \in G$ we write $\mathrm{Par}(x)$ for the element of $\Pi(n)$ to which the conjugacy class of x corresponds.

For a partition π and dimension vector d we define

$$\mathcal{F}(\pi, d) = \{F \in \mathrm{Flag}(V, d) \mid y_\pi(V_i) \subseteq V_{i-1} \text{ for all } i\}.$$

As q varies the order of $\mathcal{F}(\pi, d)$ defines a function of q, which we denote by $f(\pi, d)(q)$; note that this function depends only on π and not the choice of x_π.

Given a flag $F \in \mathrm{Flag}(V, d)$ we define P_F to be the stabilizer of F in G, i.e.

$$P_F = \{x \in G \mid x(V_i) = V_i \text{ for all } i\}.$$

It is well-known that P_F is a parabolic subgroup of G and that all parabolic subgroups of G occur in this way (for some d and F). The unipotent radical U_F of P_F is given by

$$U_F = \{x \in G \mid (x-1)(V_i) \subseteq V_{i-1} \text{ for all } i\}.$$

It is clear that for any $F \in \mathrm{Flag}(V, d)$ and any $\pi \in \Pi(n)$ there is a bijection between $\mathcal{F}(\pi, d)$ and

$$\{{}^g U_F \mid x_\pi \in {}^g U_F, \; g \in G\}.$$

Therefore, the existence of the polynomial $h_u(z)$ in Theorem 3.10 is equivalent to proving that $f(\pi, d)(q)$ is a polynomial in q.

If $x \in G$ and W is a subspace of V such that $x(W) = W$, then we write x^W for the element of $\mathrm{GL}(V/W)$ induced by x. Let $c \in \mathbb{Z}_{\geq 1}$ and let π' be a partition of $n - c$. Define

$$\mathcal{W}(\pi, \pi') = \{W \subseteq V \mid \dim W = c, \; y_\pi(W) = \{0\}, \; \mathrm{Par}(x_\pi^W) = \pi'\}.$$

As q varies, the order of $\mathcal{W}(\pi, \pi')$ defines a function $w(\pi, \pi')(q)$ of q, which only depends on π and π' (and not on the choice of x_π).

It is clear that

$$f(\pi, d)(q) = \sum_{\pi' \in \Pi(n - d_1)} w(\pi, \pi')(q) f(\pi', d')(q),$$

where $d' = (d_2, \ldots, d_r)$. So by induction we just have to show that $w(\pi, \pi')(q)$ is a polynomial in q, for all π, π'.

Define $K_\pi = \ker y_\pi$ and for each $j \in \mathbb{Z}_{\geq 0}$ define $J_{\pi, j} = K_\pi \cap y_\pi^j(V)$. Clearly, a subspace of V is killed by y_π if and only if it is contained in K_π. Let $v \in K_\pi$ and let $j \in \mathbb{Z}_{\geq 0}$ be such that $v \in J_{\pi, j} \setminus J_{\pi, j-1}$. It is easy to check that the endomorphism that x_π induces on $V/\langle v \rangle$ corresponds to the partition π^*, where $\pi_j^* = \pi_j - 1$, $\pi_{j-1}^* = \pi_{j-1} + 1$ and $\pi_i^* = \pi_i$ for all other i.

For $i = 1, \ldots, n$ we define $b_i = \sum_{j=i}^n \pi_j - \pi_j'$. The observations in the previous paragraph imply that $W \in \mathcal{W}(\pi, \pi')$ if and only if $W \subseteq K_\pi$ and $\dim(W \cap J_{\pi, i}) = b_i$ for each i. It now follows from Lemma A.2 that $w(\pi, \pi')(q)$ is a polynomial in q.

This completes the proof of existence of the polynomial $h_u(z)$ in Theorem 3.10 and therefore the proof of Theorem 4.5 for $G = \mathrm{GL}_n$.

We have not justified that $h_u(z) \in \mathbb{Z}[z]$, this reduces to checking that the polynomial $s(n, m, l)(q)$ from Lemma A.1 has integer coefficients; we leave the details to the reader.

Further, we note that it is far from evident from this proof that for associated parabolic subgroups of $G = \mathrm{GL}_n$ we get the same polynomials, cf. Corollaries 3.5 and 4.7.
