# EXOTIC HOLONOMY ON MODULI SPACES OF RATIONAL CURVES 

Quo-Shin Chi ${ }^{1}$<br>Lorenz J Schwachhöfer

November 30, 1994

#### Abstract

. Bryant [ Br ] proved the existence of torsion free connections with exotic holonomy, i.e. with holonomy that does not occur on the classical list of Berger [Ber]. These connections occur on moduli spaces $\mathcal{Y}$ of rational contact curves in a contact threefold $\mathcal{W}$. Therefore, they are naturally contained in the moduli space $\mathcal{Z}$ of all rational curves in $\mathcal{W}$.

We construct a connection on $\mathcal{Z}$ whose restriction to $\mathcal{Y}$ is torsion free. However, the connection on $\mathcal{Z}$ has torsion unless both $\mathcal{Y}$ and $\mathcal{Z}$ are flat.

We also show the existence of a new exotic holonomy which is a certain sixdimensional representation of $S l(2, \mathbb{C}) \times S l(2, \mathbb{C})$. We show that every regular $H_{3}$-connection (cf. $[\mathrm{Br}])$ is the restriction of a unique connection with this holonomy.

## §0 Introduction.

Since its introduction by Elie Cartan, the holonomy of a connection has played an important role in differential geometry. Most of the classical results are concerned with the holonomy of Levi Civita connections of Riemannian metrics. In 1955, Berger [Ber] classified the possible irreducible Riemannian holonomies and much work has been done since to study these holonomies and their applications. See [Bes] and [Sa] for a historical survey and also [J] for more recent results.

At the same time, Berger also partially classified the possible non-Riemannian holonomies of torsion free connections. However, his classification omits a finite number of possibilities, which are referred to as exotic holonomies. As of yet, the complete list of exotic holonomies is still not known.

The incompleteness of Berger's list and therefore the existence of exotic holonomies was shown by Bryant $[\mathrm{Br}]$. He investigated the irreducible representations of $S l(2, \mathbb{F}), \mathbb{F}=\mathbb{R}$ or $\mathbb{C}$. For each $d \geq 1$, we can regard $S l(2, \mathbb{F})$ as a subgroup $H_{d} \subseteq G l(d+1, \mathbb{F})$ via the (unique) $(d+1)$-dimensional irreducible representation of $S l(2, \mathbb{F})$ which will be described below. Moreover, if we let $G_{d} \subseteq G l(d+1, \mathbb{F})$ be the centralizer of $H_{d}$, then $G_{d}$ may be regarded as a representation of $G l(2, \mathbb{F})$. For $d \geq 3$, these representations do not occur on Berger's list of possible holonomies and are therefore candidates for exotic holonomies.

[^0]In his paper, Bryant showed that in the case $d=3$ torsion free connections with holonomies $H_{3}$ and $G_{3}$ do exist both if $\mathbb{F}=\mathbb{R}$ and $\mathbb{F}=\mathbb{C}$. We shall refer to them as $H_{3}$-connections ( $G_{3}$-connections respectively). From now on, we shall assume that $\mathbb{F}=\mathbb{C}$ unless stated otherwise.
$G_{3}$-structures occur naturally in the following way: let $\mathcal{W}$ be a complex contact threefold and suppose there is a rational contact curve $C$ in $\mathcal{W}$ such that the restriction of the contact line bundle $\left.L\right|_{C}$ has degree -3 . Then the moduli space $\mathcal{Y}$ of all close-by contact curves carries a torsion free $G_{3}$-connection.

Conversely, every holomorphic torsion free $G_{3}$-connection is locally equivalent to a connection on such a moduli space $\mathcal{Y}[\mathrm{Br}]$.

Before we proceed, let us briefly describe the irreducible representations of $S l(2, \mathbb{C}), G l(2, \mathbb{C})$ and $G l(2, \mathbb{C}) \times S l(2, \mathbb{C})$.

For $n \in \mathbb{N}$, let $\mathcal{V}_{n} \subseteq \mathbb{C}[x, y]$ be the ( $n+1$ )-dimensional subspace of homogeneous polynomials of degree $n$. There is an $S l(2, \mathbb{C})$-action on $\mathcal{V}_{n}$ induced by the transposed action of $S l(2, \mathbb{C})$ on $\mathbb{C}^{2}$, i.e. if $p \in \mathcal{V}_{n}$ and $A \in S l(2, \mathbb{C})$ then

$$
(A \cdot p)(x, y):=p(u, v) \quad \text { with } \quad(u, v)=(x, y) A
$$

Of course, this formula also describes an action of $G l(2, \mathbb{C})$ on $\mathcal{V}_{n}$.
The irreducible representations of $G l(2, \mathbb{C}) \times \operatorname{Sl}(2, \mathbb{C})$ can be described as follows: for $n, m \in \mathbb{N}$, we let $\mathcal{V}_{n, m}:=\mathcal{V}_{n} \otimes \mathcal{V}_{m}$. Then the action of $G l(2, \mathbb{C}) \times S l(2, \mathbb{C})$ on $\mathcal{V}_{n, m}$ is defined by

$$
(A, B) \cdot(p \otimes q):=(A \cdot p) \otimes(B \cdot q)
$$

with the actions of $G l(2, \mathbb{C})$ and $S l(2, \mathbb{C})$ on $\mathcal{V}_{n}$ and $\mathcal{V}_{m}$ from above. We define the subgroup $G_{n, m} \subseteq G l\left(\mathcal{V}_{n, m}\right)$ to be the image of this representation. Also, we let $H_{n, n} \subseteq G_{n, m}$ be the image of $S l(2, \mathbb{C}) \times S l(2, \mathbb{C}) \subseteq G l(2, \mathbb{C}) \times S l(2, \mathbb{C})$. In other words, $H_{n, m}=G_{n, m} \cap S l\left(\mathcal{V}_{n, m}\right)$.

It is well known $[\mathrm{H}]$ that these are complete lists of the irreducible representations of $S l(2, \mathbb{C}), G l(2, \mathbb{C})$ and $G l(2, \mathbb{C}) \times S l(2, \mathbb{C})$ respectively.

Given a rational contact curve $C$ in $\mathcal{W}$ as above, it turns out that its normal bundle $N_{C} \rightarrow C$ is equivalent to $\mathcal{O}(2) \oplus \mathcal{O}(2)$. By Kodaira's Deformation Theorem $[\mathrm{K}]$, the moduli space $\mathcal{Z}$ of all curves near $C$ is a smooth analytic manifold. Obviously, $\mathcal{Y} \subseteq \mathcal{Z}$.

The tangent space $T_{C} \mathcal{Z}$ can be identified with $H^{0}(\mathcal{O}(2) \oplus \mathcal{O}(2)) \cong \mathcal{V}_{1,2}$ in a natural way. Therefore, $\mathcal{Z}$ carries a canonical $G_{1,2}$-structure.

The main objective of this paper is to investigate the correlation between the $G_{3}$-structure on $\mathcal{Y}$ and the $G_{1,2}$-structure on $\mathcal{Z}$. It had been conjectured in [ Br ] that the latter structure is torsion free. However, we show that almost the exact opposite is true. Namely, we shall prove
Theorem 0.1. Let $\mathcal{W}$ be a complex contact threefold, let $C$ be a rational contact curve in $\mathcal{W}$ such that the restriction of the contact line bundle $\left.L\right|_{C}$ has degree -3 , and let $\mathcal{Z}$ ( $\mathcal{Y}$ respectively) be the moduli space of rational curves (rational contact curves respectively) in $\mathcal{W}$ close to $C$. Then the canonical $G_{1,2}$-structure on $\mathcal{Z}$ is torsion free if and only if the $G_{3}$-connection on $\mathcal{Y}$ is flat.

This means that we cannot in general expect the $G_{1,2}$-structure on $\mathcal{Z}$ to be torsion free. However, we can make some statement about its torsion.

Theorem 0.2. Let $\mathcal{W}$ be a complex threefold, let $C$ be a rational curve in $\mathcal{W}$ whose normal bundle is equivalent to $\mathcal{O}(2) \oplus \mathcal{O}(2)$ and let $\mathcal{Z}$ be the moduli space of curves in $\mathcal{W}$ close to $C$, equipped with the canonical $G_{1,2}$-structure. Then there is a subbundle $T \subseteq \Lambda^{2} T^{*} \mathcal{Z} \otimes T \mathcal{Z}$ of rank four and a unique $G_{1,2}$-connection on $\mathcal{Z}$ whose torsion is a section of $T$.

The point of Theorem 0.2. is that the rank of $\Lambda^{2} T^{*} \mathcal{Z} \otimes T \mathcal{Z}$ equals 90 , so $T$ has a large codimension. In other words, Theorem 0.2 . states that the $G_{1,2}$-structure on $\mathcal{Z}$ has "very little torsion".

Theorem 0.1. raises the questions if there are any non-flat torsion free $G_{1,2^{-}}$ structures at all.

## Theorem 0.3.

(1) The holonomy of a torsion free $G_{1,2}$-connection is contained in $H_{1,2}$. Thus, every torsion free $G_{1,2}$-structure admits a (one-parameter family of) $H_{1,2^{-}}$ reductions.
(2) A regular torsion free $H_{1,2}$-structure with full holonomy is determined by three parameters. Thus, $H_{1,2}$-connections do exists, and $H_{1,2}$ is therefore another exotic holonomy representation.

Comparing this result with Theorem 0.1. it follows that the torsion free $G_{1,2^{-}}$ connections do not arise as moduli spaces of rational curves in a contact threefold. However, we have the following characterization of $\mathrm{H}_{3}$-connections.

Theorem 0.4. Given a torsion free $G_{1,2}$-connection on a sixfold $\mathcal{Z}$ and an imbedding $\mathcal{Y} \hookrightarrow \mathcal{Z}$ of a fourfold $\mathcal{Y}$ such that the connection on $\mathcal{Z}$ restricts to a $G_{3}$ connection on $\mathcal{Y}$, then the holonomy of this restriction is contained in $H_{3}$.

Conversely, if $\mathcal{Y}$ is a fourfold with a regular torsion free $H_{3}$-connection, then there is a unique torsion free $G_{1,2}$-connection on some sixfold $\mathcal{Z}$ and an imbedding $\mathcal{Y} \hookrightarrow \mathcal{Z}$ such that the connection on $\mathcal{Z}$ restricts to the connection on $\mathcal{Y}$.

Regularity of an $H_{3}$-connection is a generic condition. For the exact definition, see $[\mathrm{Br}]$.

As an interesting consequence, we conclude that for a given regular $\mathrm{H}_{3}$-connection on $\mathcal{Y}$, there is more than one $G_{1,2}$-connection extending the $H_{3}$-connection, but exactly one of these extensions is torsion free.

The calculations in this paper make extensive use of the representation theory of $S l(2, \mathbb{C})$ and $S l(2, \mathbb{C}) \times S l(2, \mathbb{C})$, particularly an explicit version of the ClebschGordan formula. For details, we refer the reader to $[\mathrm{H}]$ and $[\mathrm{Br}]$.

The Clebsch-Gordan formula describes the irreducible decomposition of a tensor product of irreducible $S l(2, \mathbb{C})$-modules:

$$
\mathcal{V}_{m} \otimes \mathcal{V}_{n}=\bigoplus_{p=0}^{m i n(m, n)} \mathcal{V}_{m+n-2 p}
$$

A convenient tool to compute the decomposition of polynomials into their irre-
ducible components are the bilinear pairings

$$
\begin{gathered}
\langle,\rangle_{p}: V_{n} \otimes V_{m} \longrightarrow V_{n+m-2 p} \\
\langle u, v\rangle_{p}=\frac{1}{p!} \sum_{k=0}^{p}(-1)^{k}\binom{p}{k} \frac{\partial^{p} u}{\partial^{k} x \partial^{p-k} y} \frac{\partial^{p} v}{\partial^{p-k} x \partial^{k} y} \quad \text { for } \quad u \in V_{n}, v \in V_{m} .
\end{gathered}
$$

It can be shown that these pairings are $S l(2, \mathbb{C})$-equivariant and therefore are the projections onto the summands of the Clebsch-Gordan formula.

The Clebsch-Gordan formula for the irreducible representations of $\operatorname{Sl}(2, \mathbb{C}) \times$ $S l(2, \mathbb{C})$ reads:

$$
\mathcal{V}_{i_{1}, i_{2}} \otimes \mathcal{V}_{j_{1}, j_{2}}=\bigoplus_{p_{1}=0}^{\min \left(i_{1}, j_{1}\right)} \bigoplus_{p_{2}=0}^{\min \left(i_{2}, j_{2}\right)} \mathcal{V}_{i_{1}+j_{1}-2 p_{1}, i_{2}+j_{2}-2 p_{2}}
$$

On these spaces, we define the pairings

$$
\langle,\rangle_{p_{1}, p_{2}}: V_{i_{1}, i_{2}} \otimes V_{j_{1}, j_{2}} \longrightarrow V_{i_{1}+j_{1}-2 p_{1}, i_{2}+j_{2}-2 p_{2}}
$$

defined by

$$
\left\langle u_{i_{1}} \otimes v_{i_{2}}, u_{j_{1}} \otimes v_{j_{2}}\right\rangle_{p_{1}, p_{2}}:=\left(\left\langle u_{i_{1}}, u_{j_{1}}\right\rangle_{p_{1}}\right) \otimes\left(\left\langle v_{i_{2}}, v_{j_{2}}\right\rangle_{p_{2}}\right)
$$

with the pairing $\langle,\rangle_{p_{k}}$ from above.
Again, it can be shown that these pairings are $S l(2, \mathbb{C}) \times S l(2, \mathbb{C})$-equivariant and therefore are the projections onto the summands of the Clebsch-Gordan formula.

In $\S 1$, we define the notion of a $G$-structure and intrinsic torsion which will be important in $\S 3$. To demonstrate the usefulness of this concept we include several examples.

In §2, we cite Kodaira's Deformation Theorem [K] which states that, under certain circumstances, the moduli space $\mathcal{Z}$ of compact submanifolds of a given space $\mathcal{W}$ is itself a manifold. We construct a natural $G$-structure on this moduli space where $G$ is the automorphism group of the normal bundle of an element of $\mathcal{Z}$ in $\mathcal{W}$, provided some stability condition (condition (A)) is satisfied.

If $\mathcal{Z}$ is the moduli space of rational curves with positive semistable normal bundle, then condition (A) is satisfied and hence we get a $G$-structure on $\mathcal{Z}$. In particular, if $\operatorname{dim}(\mathcal{W})=3$ we obtain $G_{1, k}$-structures for some positive integer $k$.

We then construct a certain class of connections on this $G_{1, k}$-structure, called special connections. These have the property that the submanifolds $\mathcal{Z}_{p} \subseteq \mathcal{Z}$ with $p \in \mathcal{W}$, consisting of all $C \in \mathcal{Z}$ which pass through $p$, are totally geodesic. This yields some information about the torsion of special connections.

In $\S 3$, we consider a contact threefold $\mathcal{W}$, and a rational contact curve $C$. We let $\mathcal{Y}$ be the moduli space of rational contact curves close to $C$ and $\mathcal{Z}$ be the moduli space of all curves close to $C$. We then construct a $G_{k+1}$-structure on $\mathcal{Y}$ from the $G_{1, k}$-structure on $\mathcal{Z}$, and show that every connection on $\mathcal{Z}$ restricts naturally to a connection on $\mathcal{Y} \subseteq \mathcal{Z}$.

If $k=2$, i.e. if the normal bundle of each $C \in \mathcal{Z}$ is equivalent to $\mathcal{O}(2) \oplus \mathcal{O}(2)$, then - using special connections - we show that the intrinsic torsion of $\mathcal{Z}$ is a section of a certain rank four bundle. This establishes Theorem 0.2. Also, the restriction of this connection to $\mathcal{Y}$ is torsion free, hence we get a new proof that the $G_{3}$-structure on $\mathcal{Y}$ is torsion free.

In $\S 4$, we set up the structure equations for a torsion free $G_{1,2}$-connection. It turns out that the first Bianchi identity forces the holonomy of such a connection to lie in $H_{1,2} \subseteq G_{1,2}$, hence we consider the structure equations for torsion free $H_{1,2^{-}}$ connections instead. These equations and their derivatives are similar - albeit more complex - to the structure equations for $H_{3}$-connections studied in [ Br$]$. In fact, methods similar to the ones used in $[\mathrm{Br}]$ allow us to solve the structure equations explicitly. Their moduli space is then computed and we prove Theorem 0.3.

Finally, in $\S 5$ we put together the results from $\S \S 3$ and 4 . First of all, we show that if $\mathcal{Z}$ is the moduli space of rational curves in a threefold $\mathcal{W}$ and if the associated $G_{1,2}$-structure on $\mathcal{Z}$ is torsion free, then $\mathcal{Z}$ must be locally symmetric. Second, we determine those torsion free $G_{1,2}$-structures on $\mathcal{Z}$ which restrict to a $G_{3}$-structure on some $\mathcal{Y} \subseteq \mathcal{Z}$. Since none of these structures are locally symmetric, Theorem 0.1. follows. We also demonstrate Theorem 0.4. using the classification of $\mathrm{H}_{3}$-connections from [ Br ].

We conclude by discussing some questions which our investigation raises. Namely, we show that every $G_{1,2}$-structure whose torsion is a section of the bundle $T \subseteq$ $\Lambda^{2} T^{*} \mathcal{Z} \otimes T \mathcal{Z}$ from Theorem 0.2 . is locally equivalent to the moduli space of rational curves in a fivefold $\mathcal{P}$ which integrate a rank two Pfaffian system on $\mathcal{P}$.

For example, if $\mathcal{Z}$ is the moduli space of rational curves in a threefold $\mathcal{W}$, we can achieve this by letting $\mathcal{P}:=\mathbb{P} T \mathcal{W}$ with the canonical differential system [EDS], and identifying each curve $C \subseteq \mathcal{W}$ with its canonical lift $\hat{C} \subseteq \mathcal{P}$.

Of course, there are many rank two Pfaffian systems which are not locally equivalent to this contact structure on $\mathbb{P} T \mathcal{W}[\mathrm{C}]$. An interesting question is:

Which rank two Pfaffian systems on a fivefold $\mathcal{P}$ yield torsion free $G_{1,2}$-connections?

Since the moduli space of torsion free $G_{1,2}$-connections is only three dimensional by Theorem 0.3., those systems must be very special. The answer to this question will also shed some light onto the significance of $H_{3}$-connections. We shall pursue this analysis in a sequel of the present paper.

## $\S 1 G$-structures and intrinsic torsion.

Let $M^{n}$ be a (real or complex) manifold of dimension $n$. Let $\pi: \mathfrak{F} \rightarrow M$ be the coframe bundle of $M$, i.e. each $u \in \mathcal{F}$ is a linear isomorphism $u: T_{\pi(u)} M \sim \sim \mathcal{V}$, where $\mathcal{V}$ is a fixed $n$-dimensional (real or complex) vector space. Then $\mathfrak{F}$ is naturally a principal right $G l(\mathcal{V})$-bundle over $M$, where the right action $R_{g}: \mathfrak{F} \rightarrow \mathfrak{F}$ is defined by $R_{g}(u)=g^{-1} \circ u$. The tautological 1 -form $\theta$ on $\mathfrak{F}$ with values in $\mathcal{V}$ is defined by letting $\theta(\xi)=u\left(\pi_{*}(\xi)\right)$ for $\xi \in T_{u} \mathcal{F}$. For $\theta$, we have the $G l(\mathcal{V})$-equivariance $R_{g}^{*}(\theta)=g^{-1} \theta$.

Let $G \subseteq G l(\mathcal{V})$ be a closed Lie subgroup and let $\mathfrak{g} \subseteq \mathfrak{g l}(\mathcal{V})$ be the Lie algebra of $G$. A $G$-structure on $M$ is, by definition, a $G$-subbundle $F \subseteq \mathfrak{F}$. For any $G$ structure, we will denote the restrictions of $\pi$ and $\theta$ to $F$ by the same letters. Given
$A \in \mathfrak{g}$ we define the vector field $A_{*}$ on $F$ by

$$
\left(A_{*}\right)_{u}=\left.\frac{d}{d t}\left(R_{\exp (t A)}(u)\right)\right|_{t=0} .
$$

The vector fields $A_{*}$ are called the fundamental vertical vector fields on $F$. It is evident that $\pi_{*}\left(A_{*}\right)=0$ and thus $\theta\left(A_{*}\right)=0$ for all $A \in \mathfrak{g} ;$ in fact, $\left\{A_{*} \mid A \in \mathfrak{g}\right\}=$ $\operatorname{ker}\left(\pi_{*}\right)$. Moreover, for $A, B \in \mathfrak{g}$ it is well-known that $\left[A_{*}, B_{*}\right]=[A, B]_{*}$.

Let $x \in M$ and $u \in \pi^{-1}(x)$. The Lie algebra $\mathfrak{g}_{x}:=u^{-1} \mathfrak{g} u \subseteq \mathfrak{g l}\left(T_{x} M\right)$ is independent of the choice of $u$, and the union $\mathfrak{g}_{F}:=\bigcup_{x} \mathfrak{g}_{x}$ is a vector subbundle of $T^{*} M \otimes T M$.

Now we shall consider the first Spencer map $S p: \mathcal{V}^{*} \otimes \mathfrak{q l}(\mathcal{V}) \rightarrow \Lambda^{2} \mathcal{V}^{*} \otimes \mathcal{V}$ which is defined by skew-symmetrization of the first two factors of $\mathcal{V}^{*} \otimes \mathfrak{g l}(\mathcal{V}) \cong \mathcal{V}^{*} \otimes \mathcal{V}^{*} \otimes \mathcal{V}$. Since $\mathfrak{g} \subseteq \mathfrak{g l}(\mathcal{V})$ we may consider the restriction of $S p$ to $\mathcal{V}^{*} \otimes \mathfrak{g}$, and we define $\mathfrak{g}^{(1)}$ and $H^{0,2}(\mathfrak{g})$ by requiring that the following sequence be exact:

$$
\begin{equation*}
0 \longrightarrow \mathfrak{g}^{(1)} \longrightarrow \mathcal{V}^{*} \otimes \mathfrak{g} \xrightarrow{S_{p}} \Lambda^{2} \mathcal{V}^{*} \otimes \mathcal{V} \xrightarrow{p r} H^{0,2}(\mathfrak{g}) \longrightarrow 0 \tag{1-1}
\end{equation*}
$$

In the same way, we can define vector bundles $\mathfrak{g}_{F}^{(1)}$ and $H_{F}^{0,2}$ over $M$ via the exact sequence

$$
\begin{equation*}
0 \longrightarrow \mathfrak{q}_{F}^{(1)} \longrightarrow T^{*} M \otimes \mathfrak{g}_{F} \xrightarrow{S_{p}} \Lambda^{2} T^{*} M \otimes T M \xrightarrow{p r} H_{F}^{0,2} \longrightarrow 0 . \tag{1-2}
\end{equation*}
$$

From now on, we will denote points in $M$ by $x$ and points in $F$ by $u$. Moreover, $\xi, \xi^{\prime}$ denote tangent vectors on $F$ and we let $\underline{\xi}_{u}=\pi_{*}\left(\xi_{u}\right), \underline{\xi}_{u}^{\prime}=\pi_{*}\left(\xi_{u}^{\prime}\right)$ etc.

A connection on $F$ is a $g$-valued 1 -form $\omega$ on $F$ satisfying the conditions

$$
\begin{array}{ll}
\omega\left(A_{*}\right)=A & \text { for all } A \in \mathfrak{g}, \text { and } \\
R_{g}^{*}(\omega)=g^{-1} \omega g \text { for all } g \in G . \tag{1-3}
\end{array}
$$

Given a connection $\omega$, its torsion $\Theta$ is the $\mathcal{V}$-valued 2 -form given by

$$
\begin{equation*}
\Theta=d \theta+\omega \wedge \theta \tag{1-4}
\end{equation*}
$$

From (1-3) and (1-4) it follows that there is a section Tor of $\Lambda^{2} T^{*} M \otimes T M$ satisfying

$$
\begin{equation*}
\Theta\left(\xi_{u}, \xi_{u}^{\prime}\right)=u\left(\operatorname{Tor}\left(\underline{\xi}_{u}, \underline{\xi}_{u}^{\prime}\right)\right) \text { for all } \xi_{u}, \xi_{u}^{\prime} \in T_{u} F \text { and all } u \in F . \tag{1-5}
\end{equation*}
$$

The connection $\omega$ is called torsion free if $\Theta=0$.
Now let $\omega^{\prime}$ be another connection on $F$, and let $\Theta^{\prime}$ and $T o r^{\prime}$ represent its torsion. From (1-3) it follows that there is a section $\alpha$ of the bundle $T^{*} M \otimes g_{F}$ such that

$$
\begin{equation*}
\left(\omega^{\prime}-\omega\right)\left(\xi_{u}\right)=u \alpha\left(\underline{\xi}_{u}\right) u^{-1} . \tag{1-6}
\end{equation*}
$$

From (1-4) - (1-6) we obtain for the torsion

$$
\left(\Theta^{\prime}-\Theta\right)\left(\xi_{u}, \xi_{u}^{\prime}\right)=u\left(\alpha\left(\underline{\xi}_{u}\right) \cdot \underline{\xi}_{u}^{\prime}-\alpha\left(\underline{\xi}_{u}^{\prime}\right) \cdot \underline{\xi}_{u}\right)
$$

and hence,

$$
\begin{aligned}
(\text { Tor }-\operatorname{Tor})\left(\underline{\xi}, \underline{\xi^{\prime}}\right) & =\alpha(\underline{\xi}) \cdot \underline{\xi}^{\prime}-\alpha\left(\underline{\xi}^{\prime}\right) \cdot \underline{\xi} \\
& =\operatorname{Sp}(\alpha)\left(\underline{\xi}, \underline{\underline{\prime}}^{\prime}\right) \quad \text { for all } \underline{\xi}, \underline{\xi}^{\prime} \in T_{x} M .
\end{aligned}
$$

Thus, we conclude that

$$
\begin{equation*}
\operatorname{Tor}^{\prime}=\operatorname{Tor}+S_{p}(\alpha) \tag{1-7}
\end{equation*}
$$

This implies that the section $\tau:=\operatorname{pr}($ Tor $)$ of the bundle $H_{F}^{0,2}$ is independent of the choice of $\omega$ and therefore only depends on the $G$-structure $F$.

Definition 1.1. Let $\pi: F \rightarrow M$ be a $G$-structure.
(1) The vector bundle $H_{F}^{0,2}$ is called the intrinsic torsion bundle of $F$.
(2) The section $\tau$ of $H_{F}^{0,2}$ defined above is called the intrinsic torsion of $F$.
(3) $F$ is called torsion free if its intrinsic torsion $\tau=0$.

The following Proposition is then immediate from (1-7).
Proposition 1.2. Let $\pi: F \rightarrow M$ be a $G$-structure and let $\tau$ be its intrinsic torsion.
(1) If $\sigma$ is any section of $\Lambda^{2} T^{*} M \otimes T M$ such that $\operatorname{pr}(\sigma)=\tau$ then there is a connection on $F$ whose torsion section Tor equals $\sigma$.
(2) There is a torsion free connection on $F$ if and only if $F$ is torsion free.
(3) If $F$ is torsion free then there is a one-to-one correspondence between torsion free connections on $F$ and sections of $\mathfrak{g}_{F}^{(1)}$. In particular, if $\mathfrak{g}^{(1)}=0$ then the torsion free connection on $F$ is unique.

We will give some examples for this concept.

## Examples 1.3.

(1) Let $G=O(p, q) \subseteq G l(\mathcal{V})$ with $\mathcal{V}=\mathbb{R}^{n}$ and $n=p+q$. A $G$-structure on $M^{n}$ is equivalent to a pseudo-Riemannian metric on $M$ of signature $(p, q)$. One can show that $S_{p}: \mathcal{V}^{*} \otimes \mathfrak{o}(p, q) \rightarrow \Lambda^{2} \mathcal{V}^{*} \otimes \mathcal{V}$ is an isomorphism. Thus, $\mathfrak{g}^{(1)}=$ 0 and $H^{0,2}(\mathfrak{g})=0$. Then Proposition 1.2. implies that there is a unique torsion free connection on such a $G$-structure. Of course, this reproves precisely the existence and uniqueness of the Levi-Civita connection of a (pseudo-)Riemannian metric. [KN]
(2) Suppose $n=2 m$ and let $G=G l(m, \mathbb{C}) \subseteq G l(n, \mathbb{R})$. A $G$-structure on $M^{n}$ is equivalent to an almost complex structure on $M$. Then $H^{0,2}(\mathfrak{g l}(m, \mathbb{C}))=$ $\left\{\phi \in \Lambda^{2}\left(\mathbb{C}^{n}\right)^{*} \otimes_{\mathbb{R}} \mathbb{C}^{n} \mid \phi(i x, y)=-i \phi(x, y)\right\}$. Moreover, the intrinsic torsion is given by the Nijenhuis tensor. It is well known that the vanishing of this tensor, i.e. the torsion freeness of the $G$-structure, is equivalent to the integrability of the almost complex structure. [KN]
(3) Suppose $n=2 m$ and let $G=S_{p}(m) \subseteq G l(n, \mathbb{R})$. A $G$-structure on $M^{n}$ is equivalent to a non-degenerate 2 -form $\omega$ on $M$, i.e. $\omega^{m} \neq 0$. One can show that $H^{0,2}(\mathfrak{s p}(m))=\Lambda^{3} \mathbb{R}^{n}$ and that the intrinsic torsion is represented by the 3 -form $d \omega$. Thus, the $G$-structure is torsion free if anf only if $\omega$ is a symplectic form.

From these examples it should become evident that for many naturally arising $G$-structures the vanishing of the intrinsic torsion implies, in some sense, the "most natural integrability condition" of the underlying geometric structure.

## $\S 2 G$-structures on moduli spaces of compact submanifolds.

Let $\mathcal{W}$ be a complex manifold of (complex) dimension $d+r$.
Definition 2.1. By an analytic family of compact submanifolds of dimension d of $\mathcal{W}$ we shall mean a pair $(\mathcal{N}, \mathcal{Z})$ of a complex manifold $\mathcal{Z}$ and a complex analytic submanifold $\mathcal{N}$ of $\mathcal{W} \times \mathcal{Z}$ of codimension $r$ with the property that for each $t \in \mathcal{Z}$, the
intersection $\mathcal{N} \cap(\mathcal{W} \times t)$ is a compact connected submanifold of $\mathcal{W} \times t$ of dimension d.

We call $\mathcal{Z}$ the moduli space of the family $(\mathcal{N}, \mathcal{Z})$. The canonical projections of $\mathcal{N}$ onto $\mathcal{W}$ and $\mathcal{Z}$ will be denoted by $p r_{1}$ and $p r_{2}$ respectively.

For each point $t \in \mathcal{Z}$, we set

$$
C_{t} \times t=\mathcal{N} \cap(\mathcal{W} \times t)
$$

We may identify $C_{t} \times t$ with $C_{t}$ and consider $\mathcal{N}$ as a family consisting of compact submanifolds $C_{t}, t \in \mathcal{Z}$, of $\mathcal{W}$.

From now on, we shall use the notational convention $H^{i}(E):=H^{i}(C, \mathcal{O}(E))$ for a vector bundle $E \rightarrow C$.

Let $N_{t} \rightarrow C_{t}$ be the normal bundle of $C_{t}$ in $\mathcal{W}$. There is a natural imbedding $\eta_{t}: T_{t} \mathcal{Z} \hookrightarrow H^{0}\left(N_{t}\right)[\mathrm{K}]$ and we shall use $\eta_{t}$ to regard $T_{t} \mathcal{Z}$ as a subspace of $H^{0}\left(N_{t}\right)$.

Definition 2.2. An analytic family $(\mathcal{N}, \mathcal{Z})$ is called complete at $t \in \mathcal{Z}$ if $\eta_{t}$ is an isomorphism. $(\mathcal{N}, \mathcal{Z})$ is called complete if it is complete at $t$ for all $t \in \mathcal{Z}$.

We now state one of the most famous classical Theorems of the subject:
Kodaira's Deformation Theorem [K]. Let $C \subseteq \mathcal{W}$ be a compact submanifold of $\mathcal{W}$ of dimension $d$. Let $N \rightarrow C$ be the normal bundle of $C$ in $\mathcal{W}$. If $H^{1}(N)=0$ then there exists a complete analytic family $(\mathcal{N}, \mathcal{Z})$ such that $C=C_{t_{0}}$ for some $t_{0} \in \mathcal{Z}$.

Let $E \rightarrow C$ be a holomorphic vector bundle and denote the group of equivalences of $E$ with itself by $\operatorname{Aut}(E)$. Since each $\phi \in \operatorname{Aut}(E)$ induces an isomorphism $\bar{\phi}: \mathcal{O}(E) \rightarrow \mathcal{O}(E)$, we obtain a natural representation $\alpha_{*}: \operatorname{Aut}(E) \rightarrow G l\left(H^{*}(E)\right)$.

Definition 2.3. An analytic family $(\mathcal{N}, \mathcal{Z})$ is said to satisfy condition (A) if
(i) for any $t_{1}, t_{2} \in \mathcal{Z}$ the normal bundles $N_{t_{i}} \rightarrow C_{t_{i}}, i=1,2$, are equivalent, and
(ii) the representation $\alpha_{0}: \operatorname{Aut}\left(N_{t}\right) \rightarrow G l\left(H^{0}\left(N_{t}\right)\right)$ is faithful and has closed image for all $t \in \mathcal{Z}$.

Consider now a complete analytic family $(\mathcal{N}, \mathcal{Z})$ satisfying condition (A). Let $E \rightarrow C$ be a vetor bundle which is equivalent to the normal bundles $N_{t} \rightarrow C_{t}$ for all $t \in \mathcal{Z}$, and let $G:=\operatorname{Aut}(E)$. Let $\mathcal{V}:=H^{0}(E)$, and let

$$
\pi: \mathfrak{F} \rightarrow \mathcal{Z}
$$

be the $\mathcal{V}$-coframe bundle of $\mathcal{Z}$. Now consider the principal bundle $\pi: F \rightarrow \mathcal{Z}$ with

We can define a bundle imbedding $\zeta: F \hookrightarrow \mathfrak{F}$ (and thereby justify the double use of the symbol $\pi$ ) as follows: given $\imath \in F$, there is an induced isomorphism $\hat{\imath}: \mathcal{V} \rightarrow H^{0}\left(N_{t}\right)$. Then $\eta_{t} \circ \hat{\imath}: \mathcal{V} \rightarrow T_{t} \mathcal{Z}$ is also a linear isomorphism, thus $\left(\eta_{t} \circ \hat{\imath}\right)^{-1}$ is a point in $\mathfrak{F}$. From condition (A) it follows that the definition $\zeta(i):=\left(\eta_{t} \circ \hat{\imath}\right)^{-1}$ is indeed one-to-one, and moreover, the image $\zeta(F)$ is a $G$-structure on $\mathcal{Z}$. Identifying $F$ with $\zeta(F)$, we regard $F$ as a $G$-structure on $\mathcal{Z}$, where the principal $G$-action on $F$ is given by $R_{g}(\imath):=\imath \circ g$.

If we set $\underline{\theta}:=\zeta^{*}(\theta)$, where $\theta$ is the tautological form on $\mathfrak{F}$, then

$$
\begin{equation*}
\underline{\theta}\left(\xi_{z}\right)=\zeta(\imath)\left((\pi \circ \zeta)_{*}\left(\xi_{t}\right)\right) . \tag{2-2}
\end{equation*}
$$

By a slight abuse of language, we shall call $\underline{\theta}$ the tautological form on $F$.
Thus, for a complete analytic family $(\mathcal{N}, \mathcal{Z})$ satisfying condition (A), we have constructed an induced $G$-structure on the moduli space $\mathcal{Z}$.

For the remainder of this section, $(\mathcal{N}, \mathcal{Z})$ will stand for a complete analytic family of rational curves satisfying condition (A), i.e. we assume that $d=1$ and $C_{t} \cong \mathbb{P}^{1}$ for all $t \in \mathcal{Z}$.

It is well-known that every $k$-dimensional vector bundle $E \rightarrow \mathbb{P}^{1}$ satisfies $\mathcal{O}(E) \cong$ $\mathcal{O}\left(m_{1}\right) \oplus \ldots \oplus \mathcal{O}\left(m_{k}\right)$ for some integers $m_{i}, i=1, \ldots, k$. Moreover, it is not hard to show that $E$ satisfies condition (ii) in Definition 2.3. if and only if $m_{i} \geq 0$ for all $i$ and $m_{1}+\ldots+m_{k}>0$. In this case, the automorphism group decomposes as

$$
G \cong \tilde{G} \times S l(2, \mathbb{C}) \quad \text { with } \quad \tilde{G} \cong G l\left(n_{1}, \mathbb{C}\right) \times \ldots \times G l\left(n_{l}, \mathbb{C}\right)
$$

where the $n_{i}$ 's are the multiplicities of the $m_{i}$ 's. [GH]
An interesting question is to determine the intrinsic torsion of such a $G$-structure or at least to understand its vanishing. To do this, we will construct connections on $F$ and make some statements about their torsion.

Let

$$
\rho: S l(2, \mathbb{C}) \times \mathbb{P}^{1} \rightarrow \mathbb{P}^{1}
$$

denote the action of $S l(2, \mathbb{C})$ on $\mathbb{P}^{1}$ by Möbius transformations. Let us fix once and for all the reference point

$$
x_{0}:=[0: 1] \in \mathbb{P}^{1} .
$$

Consider $(\mathcal{N}, \mathcal{Z})$ as before. Let

$$
P:=\left\{\underline{\underline{\imath}}: \mathbb{P}^{1} \rightarrow C_{\ell} \mid t \in \mathcal{Z}, \underline{\underline{t}} \text { a biholomorphism }\right\}
$$

be the parameter space of $\mathcal{Z}$. Then the obvious projection

$$
\pi_{P, \mathcal{Z}}: P \rightarrow \mathcal{Z}
$$

is a principal $S l(2, \mathbb{C})$-bundle, where the principal action is defined by $R_{g}(\underline{\imath})=$ $\underline{\imath} \circ \rho(g)$. There is another projection

$$
\pi_{F, P}: F \rightarrow P
$$

which maps a bundle isomorphism $\imath: E \rightarrow N_{t}$ to the underlying biholomorphism $\underline{\imath}: \mathbb{P}^{1} \rightarrow C_{t} . \quad \pi_{F, P}$ yields another principal bundle with structure group $\tilde{G}=$ $G / S l(2, \mathbb{C})$. Finally, there is a projection

$$
\pi_{P, \mathcal{N}}: P \rightarrow \mathcal{N}
$$

which projects $\underline{\imath}: \mathbb{P}^{1} \rightarrow C_{t}$ to $\left(\underline{z}\left(x_{0}\right), t\right) \in \mathcal{N}$. This projection yields a principal bundle whose structure group is the stabilizer $G_{x_{0}} \subseteq G$.

Summarizing, we have the following commutative diagram:

Now let us fix $t_{0} \in \mathcal{Z}$ and let $C:=C_{t_{0}}$. If we denote the tangent and the normal bundle of $C$ by $\tau_{C}$ and $N_{C}$ respectively then we have the exact sequence

$$
\begin{equation*}
\left.0 \rightarrow \tau_{C} \rightarrow T \mathcal{W}\right|_{C} \rightarrow N_{C} \rightarrow 0 \tag{2-3}
\end{equation*}
$$

where $T \mathcal{W}$ denotes the holomorphic tangent bundle of $\mathcal{W}$.
It is well known that this sequence splits. Also, from (2-3) we get the exact sequence

$$
\begin{equation*}
0 \rightarrow \operatorname{Hom}\left(N_{C}, \tau_{C}\right) \rightarrow \operatorname{Hom}\left(\left.T \mathcal{W}\right|_{C}, \tau_{C}\right) \rightarrow \operatorname{Hom}\left(\tau_{C}, \tau_{C}\right) \rightarrow 0, \tag{2-4}
\end{equation*}
$$

which in turn induces the exact sequence

$$
\begin{equation*}
0 \longrightarrow H^{0}\left(\operatorname{Hom}\left(N_{C}, \tau_{C}\right)\right) \longrightarrow H^{0}\left(\operatorname{Hom}\left(\left.T \mathcal{W}\right|_{C}, \tau_{C}\right)\right) \xrightarrow{\pi^{*}} H^{0}\left(\operatorname{Hom}\left(\tau_{C}, \tau_{C}\right)\right) \tag{2-5}
\end{equation*}
$$

Let

$$
S_{C}:=\left(\pi^{*}\right)^{-1}\left(i l_{\tau_{C}}\right) \subseteq H^{0}\left(\operatorname{Hom}\left(\left.\dot{T} \mathcal{W}\right|_{C}, \tau_{C}\right)\right)
$$

where $i d_{\tau_{C}}$ is regarded as an element of $H^{0}\left(\operatorname{Hom}\left(\tau_{C}, \tau_{C}\right)\right)$. Even though $\pi^{*}$ need not be surjective in general, $S_{C}$ is non-empty; namely, $S_{C}$ consists of all splitting maps of the exact sequence (2-3). Therefore, $S_{C}$ is an affine subspace of $H^{0}\left(\operatorname{Hom}\left(\left.T \mathcal{W}\right|_{C}, \tau_{C}\right)\right)$ whose dimension equals that of $H^{0}\left(\operatorname{Hom}\left(N_{C}, \tau_{C}\right)\right)$.

Condition (A) implies that the exact sequences (2-3) - (2-5) are independent of the choice of $t_{0} \in \mathcal{Z}$, hence so is the dimension of $S_{C}$. In fact, the union

$$
S:=\bigcup_{t \in \mathcal{Z}} S_{C_{t}}
$$

forms an affine bundle over $\mathcal{Z}$, called the split-bundle of $\mathcal{Z}$.

Lemma 2.4. Given a local section $\sigma: \mathcal{U} \rightarrow S, t \mapsto \sigma_{\mathrm{t}}$ of the split-bundle $S$, let $P_{\mathcal{U}}:=\pi_{P, \mathcal{Z}}^{-1}(\mathcal{U})$. There is a unique holomorphic connection $\hat{\sigma}$ on $\pi_{P, \mathcal{Z}}: P_{\mathcal{U}} \rightarrow \mathcal{U}$ such that

$$
\begin{equation*}
\rho_{*}\left(\hat{\sigma}(\xi), 0_{x_{0}}\right)=\underline{\imath}^{-1}\left(\sigma_{t}(\underline{\xi})\right) \tag{2-6}
\end{equation*}
$$

for all $\xi \in T_{\underline{1}} P$, where $t=\pi_{P, \mathcal{Z}(\underline{2})}$ and $\underline{\xi}=\left(p r_{1} \circ \pi_{P, \mathcal{N}}\right)_{*}(\xi)$.
Proof. First of all, note that equation (2-6) is well defined: $\hat{\sigma}(\xi) \in \mathfrak{s l}(2, \mathbb{C})$, and therefore both sides are contained in $T_{x_{0}} \mathbb{P}^{1}$.

Let $\underline{\sigma}(\xi)$ be the right hand side of (2-6). Then $\underline{\sigma}$ is a holomorphic 1 -form on $P_{u}$ with values in $T_{x_{0}} \mathbb{P}^{1}$. Moreover, it is easy to see that $\rho_{*}\left(A, 0_{x_{0}}\right)=\underline{\sigma}\left(A_{*}\right)$ for all $A \in s l(2, \mathbb{C})$, where $A_{*}$ denotes the fundamental vector field corresponding to $A$.

We define a basis $\left\{A_{1}, A_{2}, A_{3}\right\}$ of $s l(2, \mathbb{C})$ by the equation

$$
\left(\begin{array}{cc}
a & b \\
c & -a
\end{array}\right)=a A_{1}+b A_{2}+c A_{3} .
$$

Clearly, $\rho_{*}\left(A_{i}, 0_{x_{0}}\right)=0$ for $i=1,2$. We define the complex-valued 1 -form $\hat{\sigma}_{3}$ by the equation $\hat{\sigma}_{3}(\xi) \rho_{*}\left(A_{3}, 0_{x_{0}}\right)=\underline{\sigma}(\xi)$, and let $\hat{\sigma}_{1}:=\mathfrak{L}_{A_{2}}\left(\hat{\sigma}_{3}\right)$ and $\hat{\sigma}_{2}:=\frac{1}{2} \mathfrak{L}_{A_{2}}\left(\hat{\sigma}_{1}\right)$, where $\mathfrak{L}$ denotes the Lie derivative.

It is left to the reader to verify that the $\mathfrak{s l}(2, \mathbb{C})$-valued 1 -form

$$
\hat{\sigma}:=\sum_{i} \hat{\sigma}_{i} A_{i}
$$

defines a connection with the desired property and that this choice is unique.
Geometrically, the interpretation of the connection $\hat{\sigma}$ is the following. Suppose we have a local section $\sigma: \mathcal{U} \rightarrow S$ and a curve $\gamma: I \rightarrow \mathcal{U} \subseteq \mathcal{Z}$ for some open set $I \subseteq \mathbb{C}, 0 \in I$. Then a horizontal lift $\bar{\gamma}: I \rightarrow P$ of $\gamma$ can be regarded as a map $\Gamma: I \times \mathbb{P}^{1} \rightarrow \mathcal{W}$ such that $\Gamma(t,-)$ parametrizes $\gamma(t)$.

Given a parametrization $\underline{\imath}: \mathbb{P}^{1} \rightarrow \gamma(0)$, we then define $\Gamma$ uniquely by requiring that
(1) $\Gamma(0, x)=\underline{\imath}(x)$ for all $x \in \mathbb{P}^{1}$, and
(2) $\sigma_{t}\left(\frac{\partial}{\partial t} \Gamma(t, x)\right)=0$ for all $t \in I$ and all $x \in \mathbb{P}^{1}$.

It is then easy to verify that the $\Gamma$ thus determined is the horizontal lift of $\gamma$ w.r.t. the connection $\hat{\sigma}$.

Definition 2.5. A holomorphic connection $\omega$ on $\pi: F \rightarrow \mathcal{Z}$ is called special if there exists a holomorphic section $\sigma$ of the split-bundle $S \rightarrow \mathcal{Z}$, and a $\mathfrak{g}$-valued 1-form $\tilde{\omega}$ on $F$ such that

$$
\omega=\tilde{\omega}+\hat{\sigma}
$$

with $\hat{\sigma}$ as in Lemma 2.4. Here, we use the decomposition $\mathfrak{g} \cong \tilde{\mathfrak{g}} \oplus \boldsymbol{s l}(2, \mathbb{C})$.

Proposition 2.6. Let $(\mathcal{N}, \mathcal{Z})$ and $\pi: F \rightarrow \mathcal{Z}$ be as before. Every $t_{0} \in \mathcal{Z}$ has a neighborhood $\mathcal{U} \subseteq \mathcal{Z}$ such that the restricted bundle $\pi: F_{\mathcal{U}} \rightarrow \mathcal{U}$ with $F_{U}:=\pi^{-1}(\mathcal{U})$ admits a special connection.

Proof. The proof is almost obvious: choose $\mathcal{U}$ sufficiently small such that $\pi: F_{\mathcal{U}} \rightarrow$ $\mathcal{U}$ admits a holomorphic connection $\underline{\omega}=\tilde{\omega}+\phi$ where $\tilde{\omega}$ and $\phi$ are holomorphic 1 -forms with values in $\mathfrak{g}$ and $\mathfrak{s l}(2, \mathbb{C})$ respectively. After shrinking $\mathcal{U}$ we may also assume that the split-bundle $S$ admits a holomorphic section $\sigma$ over $\mathcal{U}$. Then the form $\omega:=\tilde{\omega}+\hat{\sigma}$ is a special connection.

An important characterization of special connections comes from the following
Proposition 2.7. For every $p \in \mathcal{W}$, let $\mathcal{Z}_{p}:=\left\{t \in \mathcal{Z} \mid p \in C_{t}\right\}$. If $\mathcal{Z}_{p} \neq \emptyset$ then $\mathcal{Z}_{p}$ is a smooth submanifold of $\mathcal{Z}$ with $\operatorname{codim}\left(\mathcal{Z}_{p}\right)=\operatorname{dim}(\mathcal{W})-1$. The tangent space of $\mathcal{Z}_{p}$ at $t \in \mathcal{Z}_{p}$ is $H^{0}\left(C_{t}, \mathcal{O}\left(N_{t}\right)-p\right) \subseteq H^{0}\left(N_{t}\right) \cong T_{t} \mathcal{Z}$. Moreover, $\mathcal{Z}_{p}$ is totally geodesic w.r.t. any special connection $\omega$.

Proof. The proof of the first two parts is left to the reader.
To show that $\mathcal{Z}_{p}$ is totally geodesic, let $t_{0} \in \mathcal{Z}_{p}$ and pick a biholomorphism $\underline{\imath}_{0}: \mathbb{P}^{1} \rightarrow C_{t_{0}}$ such that $\underline{\imath}_{0}\left(x_{0}\right)=p$. Then $\underline{\iota}_{0} \in \pi_{P, \mathcal{Z}}^{-1}\left(t_{0}\right)$. We also pick a bundle isomorphism $\imath_{0}: E \rightarrow N_{t_{0}}$ such that $\tau_{0} \in \pi_{F, P}^{-1}\left(\imath_{0}\right)$. Here, $E \rightarrow \mathbb{P}^{1}$ is a vector bundle which is isomorphic to $\mathcal{O}\left(N_{t}\right) \rightarrow C_{t}$ for all $t \in \mathcal{Z}$.

Let $\omega=\tilde{\omega}+\hat{\sigma}$ be a special connection on $F$ where $\sigma$ is a section of the split-bundle $S$. Let $I \subseteq \mathbb{C}$ be an open neighborhood of 0 , and consider a geodesic $\gamma: I \rightarrow \mathcal{Z}$ with $\gamma(0)=t_{0}$ and $\gamma^{\prime}(0) \in T_{t_{0}} \mathcal{Z}_{\mu}$. Let $\tilde{\tilde{\gamma}}: I \rightarrow P$ and $\tilde{\gamma}: I \rightarrow F$ be the horizontal lifts of $\gamma$ to $P$ and $F$ respectively with $\underline{\tilde{\gamma}}(0)=\underline{\imath}_{0}$ and $\tilde{\gamma}(0)=\imath_{0}$.

Define $\Gamma: I \times \mathbb{P}^{1} \rightarrow \mathcal{W}$ by $\Gamma(z, x):=\underline{\tilde{\gamma}}(z)(x)$. Since $\tilde{\gamma}$ is horizontal and thus, in particular, $\hat{\sigma}\left(\underline{\tilde{\gamma}}^{\prime}(z)\right)=0$ for all $z$, it follows that

$$
\begin{equation*}
\sigma_{\gamma(z)}\left(\frac{\partial}{\partial z} \Gamma\left(z, x_{0}\right)\right)=0 \quad \text { for all } z \in I . \tag{2-7}
\end{equation*}
$$

On the other hand, since $\gamma$ is a geodesic, we conclude from (2-2) that $\zeta(\tilde{\gamma}(z))\left(\gamma^{\prime}(z)\right) \in H^{0}(E)$ is independent of $z$ and thus vanishes at $x_{0}$ for all $z$. It follows that

$$
\begin{equation*}
\frac{i}{i z} \Gamma\left(z, x_{0}\right) \text { is tangent to } C_{\gamma(z)} \text { for all } z \in I . \tag{2-8}
\end{equation*}
$$

But (2-7) and (2-8) together imply that

$$
\frac{\partial}{\partial z} \Gamma\left(z, x_{0}\right)=0 \quad \text { for all } z \in I,
$$

and thus $\Gamma\left(z, x_{0}\right)=p$ for all $z \in I$. But this means $\gamma(z) \in \mathcal{Z}_{p}$ for all $z$ and this completes the proof.

This Proposition yields immediately
Corollary 2.8. If $\omega$ is a special connection on $\mathcal{Z}$ and Tor: $\Lambda^{2} H^{0}\left(N_{t}\right) \rightarrow H^{0}\left(N_{t}\right)$ is its torsion then

$$
\operatorname{Tor}\left(\Lambda^{2} H^{0}\left(C_{t}, \mathcal{O}\left(N_{t}\right)-p\right)\right) \subseteq H^{0}\left(C_{t}, \mathcal{O}\left(N_{t}\right)-p\right)
$$

for all $p \in C_{t}$.
Since torsion is a local concept, Proposition 2.6. together with Corollary 2.8 will allow us to make some assumptions about the intrinsic torsion of $F$. This will be applied in the following sections.

We shall also need one further property of special connections. Its proof is immediate from (2-2) and (2-6).
Proposition 2.9. Let $\underline{\mathcal{V}}:=H^{0}\left(\mathbb{P}^{1}, \mathcal{O}(k) \oplus \mathcal{O}(k)-x_{0}\right)$ be the space of global sections of $\mathcal{O}(k) \oplus \mathcal{O}(k)$ which vanish at $x_{0}$ and let $\mathfrak{g}^{\prime}:=\tilde{\mathfrak{g}} \oplus \mathfrak{h}_{x_{0}} \subseteq \mathfrak{g}$ where $\mathfrak{h}_{x_{0}} \subseteq \mathfrak{s l}(2, \mathbb{C})$ is the infinitesimal stabilizer of $x_{0}$ under $\rho$. Consider the projection $p r_{1} \circ \pi_{F, \mathcal{N}}: F \rightarrow$ $\mathcal{W}$. If $\omega$ is a special connection on $F$ then

$$
\operatorname{ker}\left(p r_{1} \circ \pi_{F, \mathcal{N}}\right) *=\left\{\xi \in T F \mid(\theta+\omega)(\xi) \in \underline{\mathcal{V}} \oplus \mathfrak{g}^{\prime}\right\}
$$

## §3 Moduli spaces of rational contact curves.

In this entire section, we shall assume that $\operatorname{dim}(\mathcal{W})=3$ and that $\mathcal{W}$ carries a holomorphic contact structure, i.e. a holomorphic line bundle $L \subseteq T^{*} \mathcal{W}$ with the property that for every non-vanishing local section $\kappa$ in $L$, the local 3 -form $\kappa \wedge d \kappa$ does not vanish anywhere.

By a standard notational ambiguity we will denote by $\mathcal{O}(n)$ both the (unique) line bundle of degree $n$ over $\mathbb{P}^{1}$ and the sheaf of germs of holomorphic sections of this line bundle.

Let us first of all cite the following
Proposition 3.1. $[\mathrm{Br}]$ Let $\mathcal{W}$ denote a complex contact 3-fold with contact line bundle $L \subseteq T^{*} \mathcal{W}$. Let $C \subseteq \mathcal{W}$ be an imbedded rational contact curve, and suppose that $\left.L\right|_{C} \cong \mathcal{O}(-k-1)$ for some integer $k \geq 0$. Then
(1) $N_{C} \cong \mathcal{O}(k) \oplus \mathcal{O}(k)$, where $N_{C}$ denotes the normal bundle of $C$ in $\mathcal{W}$,
(2) the moduli space $\mathcal{Z}$ of imbedded rational curves is smooth and of complex dimension $2 k+2$ near $C$, and
(3) the subspace $\mathcal{Y} \subseteq \mathcal{Z}$ of rational contact curves in $\mathcal{W}$ is a smooth analytic submanifold of $\mathcal{Z}$ of dimension $k+2$.

For the remainder of this section we shall assume that $k>0$. It follows that $\mathcal{Z}$ is a complete analytic family of rational curves satisfying condition (A).

Let $E:=\mathcal{O}(k) \oplus \mathcal{O}(k)$. Then

$$
G:=A u t(E)=G l(2, \mathbb{C}) \times S l(2, \mathbb{C}),
$$

where the first factor $G l(2, \mathbb{C})$ consists of those automorphisms which fix the base space $\mathbb{P}^{1}$, and the second factor $S l(2, \mathbb{C})$ consists of automorphisms which are induced by Möbius transformations of $\mathbb{P}^{\mathbf{1}}$. As an $\operatorname{Aut}(E)$-module, $T_{C} \mathcal{Z} \cong H^{\circ}(\mathcal{O}(k) \oplus$ $\mathcal{O}(k)) \cong \mathcal{V}_{1, k}$.

Let $L^{\perp} \subseteq T \mathcal{W}$ be the 2-plane bundle anihilated by the sections of $L$. For local sections $\xi, \xi^{\prime}$ and $\kappa$ of $L^{\perp}$ and $L$ respectively, the pairing $\left(\xi \wedge \xi^{\prime}, \kappa\right) \mapsto d \kappa\left(\xi, \xi^{\prime}\right)$ is
easily seen to be tensorial and non-degenerate, hence induces a bundle isomorphism $\Lambda^{2}\left(L^{\perp}\right) \xrightarrow{\cong} L^{*}$. Also, we have the canonical short exact sequence

$$
\begin{equation*}
0 \longrightarrow L^{\perp} \longrightarrow T W \longrightarrow L^{*} \longrightarrow 0 \tag{3-1}
\end{equation*}
$$

where $T \mathcal{W}$ is the holomorphic tangent bundle of $\mathcal{W}$.
Now let $C \in \mathcal{Y} \subseteq \mathcal{Z}$. Since $C$ is a contact curve, we have an inclusion $0 \rightarrow \tau \rightarrow$ $L_{\mid C}^{\perp}$, where $\tau$ is the tangent bundle of $C$, and from there it follows that

$$
\tau \otimes\left(L_{\mid C}^{\perp} / \tau\right) \cong \Lambda^{2}\left(L_{\mid C}^{\perp}\right) \cong L_{\mid C}^{*} \cong \mathcal{O}(k+1)
$$

Thus, since $\tau \cong \mathcal{O}(2)$, we must have $L_{\mid C}^{\perp} / \tau \cong \mathcal{O}(k-1)$. From (3-1) we also have the short exact sequence

$$
\begin{equation*}
0 \longrightarrow L_{\mid C}^{\perp} / \tau \longrightarrow N_{C} \longrightarrow L_{\mid C}^{*} \longrightarrow 0 \tag{3-2}
\end{equation*}
$$

where $N_{C}$ denotes the normal bundle of $C$ in $\mathcal{W}$.
Since $H^{1}\left(L_{\mid C}^{\perp} / \tau\right) \cong H^{1}(\mathcal{O}(k-1))=0,(3-2)$ induces the short exact sequence

$$
0 \longrightarrow H^{0}\left(L_{\mid C}^{\perp} / \tau\right) \xrightarrow{\imath} H^{0}\left(N_{C}\right) \xrightarrow{p r} H^{0}\left(L_{\mid C}^{*}\right) \longrightarrow 0 .
$$

Lemma 3.2. Let $C \in \mathcal{Y}$ and $\xi \in T_{C} \mathcal{Y} \subseteq T_{C} \mathcal{Z} \cong H^{0}\left(N_{C}\right)$. If $p r(\xi) \in H^{0}\left(L_{\mid C}^{*}\right)$ vanishes at $p \in C$ of order at least two, then $\xi-$ regarded as a section of $N_{C}-$ vanishes at $p$.

Proof. Given $\xi \in T_{C} \mathcal{Y}$ as above, we pick a holomorphic curve $\gamma: I \rightarrow \mathcal{Y}$ with $\gamma(0)=$ $C$ and $\gamma^{\prime}(0)=\xi$ where $I \subseteq \mathbb{C}$ is an open neighborhood of 0 . Let $\Gamma: I \times \mathbb{P}^{1} \rightarrow \mathcal{W}$ be a holomorphic map such that $\Gamma(t,-)$ is a parametrization of $\gamma(t)$ for all $t$. We may assume $\Gamma\left(0, x_{0}\right)=p$ with $x_{0}:=[0: 1] \in \mathbb{P}^{1}$.

First, suppose that $\Gamma$ is a local biholomorphism from a neighborhood of ( $0, x_{0}$ ) to $U \subseteq \mathcal{W}$. Then the holomorphic vector fields

$$
X:=\frac{\partial \Gamma}{\partial t}(t, x) \quad \text { and } \quad Y:=\frac{\partial \Gamma}{\partial x}(t, x)
$$

are well defined on $U$.
Let $\kappa$ be a local contact form on $U$. Then we have

$$
d \kappa\left(X_{p}, Y_{p}\right)=X_{p}(\kappa(Y))-Y_{p}(\kappa(X))-\kappa\left([X, Y]_{p}\right)
$$

But all three terms on the right hand side vanish: the first one vanishes because $Y$ is tangent to the contact curves $\gamma(t)$, thus $\kappa(Y) \equiv 0$. The second one vanishes because - by hypothesis - the function $\kappa(X):(U \cap C) \rightarrow \mathbb{C}$ vanishes of order two at $p$. Finally, $[X, Y]=0$ from the definition of $X$ and $Y$, thus the third term vanishes as well.

The vanishing of $\operatorname{pr}(\xi)$ at $p$ implies that $X_{p} \in L_{p}^{\perp}$, hence $X_{p}, Y_{p}$ span $L_{p}^{\perp}$. But this together with $d \kappa\left(X_{p}, Y_{p}\right)=0$ implies that $(\kappa \wedge d \kappa)_{p}=0$ which is impossible.

Therefore, $\Gamma$ is not a local biholomorphism at $\left(0, x_{0}\right)$, i.e. $\frac{\partial \Gamma}{\partial t}\left(0, x_{0}\right)$ must be tangent to $C$. But this implies exactly that $\xi$ vanishes at $p$.

Corollary 3.3. For every $C \in \mathcal{Y}$, the restriction $p r: T_{C} \mathcal{Y} \rightarrow H^{0}\left(L_{\mid C}^{*}\right)$ is an isomorphism.

Proof. From Proposition 3.1. we know that $\operatorname{dim}\left(T_{C} \mathcal{Y}\right)=k+2=\operatorname{dim}\left(H^{0}\left(L_{1 C}^{*}\right)\right)$, and from Lemma 3.2. it follows that $\operatorname{ker}(p r) \cap T_{C} \mathcal{Y}=0$.

Recall that the sequence (3-2) is equivalent to

$$
0 \rightarrow \mathcal{O}(k-1) \rightarrow \mathcal{O}(k) \oplus \mathcal{O}(k) \rightarrow \mathcal{O}(k+1) \rightarrow 0
$$

It is easy to show that - up to equivalence - the maps in this exact sequence are uniquely determined. More specifically, one can show that for every $C \in \mathcal{Y}$, there are bundle isomorphisms $\phi_{C}, \phi_{C}^{\prime}$ and $\phi_{C}^{\prime \prime}$ such that the diagram

commutes, and for the induced commutative diagram

we have $\underline{z}\left(u_{k-1}\right)=x \otimes\left(y \cdot u_{k-1}\right)-y \otimes\left(x \cdot u_{k-1}\right)$, and $\underline{p r}\left(u_{1} \otimes v_{k}\right)=u_{1} \cdot v_{k}$ for all $u_{i}, v_{i} \in \mathcal{V}_{i}$. Here, we used the natural identifications $H^{0}(\mathcal{O}(n)) \cong \mathcal{V}_{n}$ and $H^{0}(\mathcal{O}(n) \oplus \mathcal{O}(n)) \cong \mathcal{V}_{1, n}$ for any integer $n \geq 0$.

Let us define the vector subspaces $\mathcal{V}^{\prime}$ and $\mathcal{V}^{\prime \prime}$ of $\mathcal{V}_{1, k}$ by

$$
\mathcal{V}^{\prime}:=\left\{x \otimes u_{x}+y \otimes u_{y} \mid u \in \mathcal{V}_{k+1}\right\},
$$

where $u_{x}$ and $u_{y}$ denote partial derivatives, and

$$
\mathcal{V}^{\prime \prime}:=\underline{\imath}\left(\mathcal{V}_{k-1}\right)=\left\{x \otimes(y \cdot u)-y \otimes(x \cdot u) \mid u \in \mathcal{V}_{k-1}\right\} .
$$

Then $\mathcal{V}_{1, k}=\mathcal{V}^{\prime} \oplus \mathcal{V}^{\prime \prime}$ is easily verified.
Proposition 3.4. Let $C \in \mathcal{Y} \subseteq \mathcal{Z}$ be a rational contact curve and consider bundle isomorphisms $\phi_{C}, \phi_{C}^{\prime}$ and $\phi_{C}^{\prime \prime}$ which induce the commutative diagrams (3-3) and (3-4). Then we have

$$
\begin{equation*}
\phi_{C}^{*}\left(\mathcal{V}^{\prime}\right)=T_{C} \mathcal{Y} \quad \text { and } \quad \phi_{C}^{*}\left(\mathcal{V}^{\prime \prime}\right)=\imath\left(H^{0}\left(L_{\mid C}^{\perp} / \tau\right)\right) \tag{3-5}
\end{equation*}
$$

Proof. The map $\eta: \mathcal{V}_{k+1} \rightarrow \mathcal{V}_{1, k}$ given by $\eta(u):=\frac{1}{k+1}\left(x \otimes u_{x}+y \otimes u_{y}\right)$ splits the top exact sequence of (3-4). Thus, Corollary 3.3. implies that there is a map $\delta: \mathcal{V}_{k+1} \rightarrow \mathcal{V}_{k-1}$ such that $T_{C} \mathcal{Y}=\phi_{C}^{*}\left(\left\{(\eta+\underline{\imath} \circ \delta)(u) \mid u \in \mathcal{V}_{k+1}\right\}\right)$.

Since $\mathcal{V}_{k+1}^{*} \otimes \mathcal{V}_{k-1} \cong \mathcal{V}_{2 k} \oplus \mathcal{V}_{2 k-2} \oplus \ldots \oplus \mathcal{V}_{2}$ it follows that there are polynomials $v_{i} \in \mathcal{V}_{i}, i=2,4, \ldots 2 k$ such that

$$
\delta(u)=\left\langle u, v_{2 k}\right\rangle_{k+1}+\left\langle u, v_{2 k-2}\right\rangle_{k}+\ldots+\left\langle u, v_{2}\right\rangle_{2} .
$$

From Lemma 3.2. and an easy calculation we conclude that $\delta$ must satisfy the following condition:

$$
\begin{equation*}
\text { if } r^{2} \mid u \text { for some } r \in \mathcal{V}_{1}, u \in \mathcal{V}_{k+1} \text { then } r \mid \delta(u) \tag{3-6}
\end{equation*}
$$

Using the $S l(2, \mathbb{C})$ equivariance of $\langle-,-\rangle$ we compute that for any $r \in \mathcal{V}_{1}, r \mid \delta\left(r^{k+1}\right)$ if and only if $r \mid v_{2 k}$. Thus, (3-6) implies that every $r \in \mathcal{V}_{1}$ divides $v_{2 k}$, hence $v_{2 k}=0$.

Next, a similar calculation shows that $r \| \delta\left(r^{k} s\right)$ for all $s \in \mathcal{V}_{1}$ if and only if $r v_{2 k-2}$. Again, this together with (3-6) implies $v_{2 k-2}=0$.

Continuing with similar arguments, we see successively that $v_{2 k}=v_{2 k-2}=\ldots=$ $v_{2}=0$, thus $\delta=0$, and this shows the first equation in (3-5). The second equation is immediate from the commutativity of (3-4).
Proposition 3.5. Let $F_{y}:=\pi^{-1}(\mathcal{Y})$ with the principal $G$-bundle $\pi: F \rightarrow \mathcal{Z}$ from (2-1) and let $\pi \mathcal{Y}: \mathfrak{F} y \rightarrow \mathcal{Y}$ denote the total $\mathcal{V}_{k+1}$-coframe bundle of $\mathcal{Y}$. The set

$$
\hat{F}:=\left\{\begin{array}{l|c}
\phi_{C}: \mathcal{O}(k) \oplus \mathcal{O}(k) \rightarrow N_{C} & \begin{array}{c}
C \in \mathcal{Y}, \phi_{C} \text { a bundle isomorphism } \\
\text { which satisfies }(3-5)
\end{array}
\end{array}\right\} \subseteq F_{y}
$$

is a reduction of $F_{Y}$ with structure group

$$
G^{\Delta}:=\left\{(c \cdot A, A) \mid c \in \mathbb{C}^{*}, A \in S l(2, \mathbb{C})\right\} \subseteq G .
$$

Moreover, the map

$$
\begin{aligned}
\zeta: \hat{F} & \rightarrow \mathfrak{F} y \\
\phi_{C} & \mapsto\left(\underline{p r} \circ\left(\phi_{C}^{*}\right)^{-1}: T_{C} \mathcal{Y} \rightarrow \mathcal{V}_{k+1}\right)
\end{aligned}
$$

is an imbedding, and the image $\zeta(\hat{F}) \subseteq \mathfrak{F} y$ is a $G_{k+1}$-structure on $\mathcal{Y}$.
Proof. The proof is straightforward: first of all, by our previous discussion we know that $\pi^{-1}(C) \cap \hat{F} \neq \emptyset$ for all $C \in \mathcal{Y}$. Moreover, if $\phi_{C}^{1}, \phi_{C}^{2} \in \hat{F}_{C}$, then $\psi:=$ $\left(\phi_{C}^{1}\right)^{-1} \circ \phi_{C}^{2} \in \operatorname{Aut}(\mathcal{O}(k) \oplus \mathcal{O}(k))$ must satisfy $\psi^{*}\left(\mathcal{V}^{\prime}\right)=\mathcal{V}^{\prime}$ and $\psi^{*}\left(\mathcal{V}^{\prime \prime}\right)=\mathcal{V}^{\prime \prime}$. This is the case precisely if $\psi \in G^{\Delta}$. Thus $\hat{F}$ is a $G^{\Delta}$-reduction of $F_{\mathcal{y}}$.

The verification of the stated properties of $\zeta$ is left to the reader.
By abuse of notation, we shall identify $\hat{F}$ with $\zeta(\hat{F})$ and thus regard $\hat{F}$ as a $G_{k+1}$-structure on $\mathcal{Y}$. The tautological 1-form of $\pi: \hat{F} \rightarrow \mathcal{Y}$ is then given by

$$
\hat{\theta}=\underline{p r} \circ\left(\left.\theta\right|_{\dot{F}}\right) .
$$

The decomposition $\mathcal{V}_{1, k}=\mathcal{V}^{\prime} \oplus \mathcal{V}^{\prime \prime}$ induces the decomposition

$$
\mathcal{V}_{1, k}^{*} \otimes \mathcal{V}_{1, k}=\left(\mathcal{V}^{\prime *} \otimes \mathcal{V}^{\prime}\right) \oplus\left(\mathcal{V}^{\prime *} \otimes \mathcal{V}^{\prime \prime}\right) \oplus\left(\mathcal{V}^{\prime \prime *} \otimes \mathcal{V}^{\prime}\right) \oplus\left(\mathcal{V}^{\prime \prime *} \otimes \mathcal{V}^{\prime \prime}\right)
$$

Projection onto the first direct summand composed with conjugation by pr| $\mathcal{V}^{\prime}$ yields a homomorphism

$$
p: \mathfrak{g l}\left(\mathcal{V}_{1, k}\right) \rightarrow \mathfrak{g l}\left(\mathcal{V}_{k+1}\right) .
$$

It is not hard to verify that the 1 -form

$$
\hat{\omega}:=\left.(p \circ \omega)\right|_{\hat{F}}
$$

yields a connection on $\pi: \hat{F} \rightarrow \mathcal{Y}$.

## Definition 3.6.

(1) A $G_{1, k}$-connection is a triple $(\pi: F \rightarrow \mathcal{Z}, \theta, \omega)$ of a $G_{1, k}$-reduction $F$ of $\mathcal{Z}$ and the tautological and connection 1 -forms $\theta$ and $\omega$.
(2) Likewise, a $G_{k+1}$-connection is a triple ( $\pi: \hat{F} \rightarrow \mathcal{Y}, \hat{\theta}, \hat{\omega}$ ) of a $G_{k+1}$-reduction $\hat{F}$ of $\mathcal{Y}$ and the tautological and connection 1 -forms $\hat{\theta}$ and $\hat{\omega}$.
(3) Suppose ( $\pi: F \rightarrow \mathcal{Z}, \theta, \omega$ ) and ( $\pi: \hat{F} \rightarrow \mathcal{Y}, \hat{\theta}, \hat{\omega}$ ) are a $G_{1, k}$-connection and a $G_{k+1}$-connection respectively and suppose there is an injective bundle map

such that $\hat{\theta}=\left.\underline{p r} \circ \theta\right|_{\hat{F}}$ and $\hat{\omega}=\left.p \circ \omega\right|_{\hat{F}}$.
Then $(\pi: \hat{F} \rightarrow \mathcal{Y}, \hat{\theta}, \hat{\omega})$ is called a restriction of $(\pi: F \rightarrow \mathcal{Z}, \theta, \omega)$, whereas $(\pi: F \rightarrow \mathcal{Z}, \theta, \omega)$ is called an extension of $(\pi: \hat{F} \rightarrow \mathcal{Y}, \hat{\theta}, \hat{\omega})$.

The following Proposition is straightforward and the proof is omitted.
Proposition 3.7. If the $G_{1, k}$-connection ( $\pi: F \rightarrow \mathcal{Z}, \theta, \omega$ ) is an extension of the $G_{k+1}$-connection ( $\hat{\pi}: \hat{F} \rightarrow \mathcal{Y}, \hat{\theta}, \hat{\omega}$ ) and if $\Theta$ and $\hat{\Theta}$ denote the torsion of $\omega$ and $\hat{\omega}$ respectively then

$$
\hat{\Theta}=\left.p r \circ \Theta\right|_{\hat{F}}
$$

Definition 3.8. A connection on $\pi y: \hat{F} \rightarrow \mathcal{Y}$ is called special if it is the restriction of a special connection on $\pi: F \rightarrow \mathcal{Z}$.

Of course, from our discussion preceding Definition 3.6. we know that if $\mathcal{Z}$ is the moduli space of rational curves in $\mathcal{W}$ whose normal bundle is equivalent to $\mathcal{O}(k) \oplus \mathcal{O}(k)$ and if $\mathcal{Y} \subseteq \mathcal{Z}$ is the subset of contact curves then every connection on $\pi: F \rightarrow \mathcal{Z}$ has a restriction to the $G_{k+1}$-structure $\pi: \hat{F} \rightarrow \mathcal{Y}$.

Let us now investigate the intrinsic torsion of both the $G_{1, k}$-structure $\pi: F \rightarrow \mathcal{Z}$ and the $G_{k+1^{-s t r}}$-sture $\pi_{y}: \hat{F} \rightarrow \mathcal{Y}$. The Spencer sequence (1-1) reads

$$
\begin{equation*}
0 \longrightarrow \mathfrak{g}_{1, k}^{(1)} \longrightarrow \mathcal{V}_{1, k}^{*} \otimes \mathfrak{g}_{1, k} \xrightarrow{S p} \Lambda^{2} \mathcal{V}_{1, k}^{*} \otimes \mathcal{V}_{1, k} \longrightarrow H^{0,2}\left(\mathfrak{g}_{1, k}\right) \longrightarrow 0 \tag{3-7}
\end{equation*}
$$

and

$$
0 \longrightarrow \mathfrak{g}_{k+1}^{(1)} \longrightarrow \mathcal{V}_{k+1}^{*} \otimes \mathfrak{g}_{k+1} \xrightarrow{S_{p}} \Lambda^{2} \mathcal{V}_{k+1}^{*} \otimes \mathcal{V}_{k+1} \longrightarrow H^{0,2}\left(\mathfrak{g}_{k+1}\right) \longrightarrow 0
$$

Lemma 3.9. If $k \geq 2$ then $\mathfrak{g}_{1, k}^{(1)}=0$ and $\mathfrak{g}_{k+1}^{(1)}=0$.
Proof. Let $\varphi \in \mathfrak{g}_{1, k}^{(1)}$. We regard $\varphi$ as a linear map $\varphi: \mathcal{V}_{1, k} \rightarrow \mathfrak{g}_{1, k}$. Pick two arbitrary bases $\left(r_{1}, r_{2}\right)$ and $\left(s_{1}, s_{2}\right)$ of $\mathcal{V}_{1}$. Then the set $\left\{r_{i} \otimes s_{1}^{k-j} s_{2}^{j} \mid i=1,2, j=\right.$ $0, \ldots k\}$ forms a basis of $\mathcal{V}_{1, k}$. We have

$$
\left(\varphi\left(r_{1} \otimes s_{1}^{k}\right)\right)\left(r_{2} \otimes s_{2}^{k}\right)-\left(\varphi\left(r_{2} \otimes s_{2}^{k}\right)\right)\left(r_{1} \otimes s_{1}^{k}\right)=0
$$

If we let $\varphi\left(r_{i} \otimes s_{i}^{k}\right):=\left(A_{i}, B_{i}\right)$ for $i=1,2$ be the decomposition in $\mathfrak{g}_{1, k} \cong$ $\mathfrak{g l}(2, \mathbb{C}) \oplus \mathfrak{s l}(2, \mathbb{C})$, then this equation reads

$$
\begin{equation*}
\left(\left(A_{1} \cdot r_{2}\right) \otimes s_{2}^{k}\right)+\left(r_{2} \otimes\left(B_{1} \cdot s_{2}^{k}\right)\right)-\left(\left(A_{2} \cdot r_{1}\right) \otimes s_{1}^{k}\right)-\left(r_{1} \otimes\left(B_{2} \cdot s_{1}^{k}\right)\right)=0 . \tag{3-8}
\end{equation*}
$$

Note that $B_{1} \cdot s_{2}^{k} \in \operatorname{span}\left\{s_{1} s_{2}^{k-1}, s_{2}^{k}\right\}$. Taking the ( $r_{2} \otimes s_{1} s_{2}^{k-1}$ )-component of (3-8) w.r.t. the above basis we conlude that $s_{2}^{k}$ is an eigenvector of $B_{1}$. Since this is true for any $s_{2}$ which is linearly independent of $s_{1}$, it follows that $B_{1}$ is a multiple of the identity. On the other hand, $\operatorname{trace}\left(B_{1}\right)=0$. Thus, we have $B_{1}=0$.

Likewise, $A_{1}=0$, hence $\varphi\left(r_{1} \otimes s_{1}^{k}\right)=0$ for arbitrary $r_{1}, s_{1} \in \mathcal{V}_{1}$. Since elements of this form span all of $\mathcal{V}_{1, k}, \varphi=0$ follows.

The proof of the second statement is of similar nature but simpler. We omit the details.

To calculate the irreducible components of (3-7), note that as a $G$-module, $\mathfrak{g}_{1, k} \cong$ $\mathcal{V}_{0,0} \oplus \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$. In fact, the equivalence is determined by the equation

$$
\begin{equation*}
\left(p_{0,0}+p_{2,0}+p_{0,2}\right) \cdot q_{1, k}:=\left\langle p_{0,0}, q_{1, k}\right\rangle_{0,0}+\left\langle p_{2,0}, q_{1, k}\right\rangle_{1,0}+\left\langle p_{0,2}, q_{1, k}\right\rangle_{0,1} \tag{3-9}
\end{equation*}
$$

for all $p_{i, j} \in \mathcal{V}_{i, j}$ and $q_{1, k} \in \mathcal{V}_{1, k}$.
For the rest of this section we shall assume that $k=2$. In this case, a calculation shows that the decomposition of the Spencer sequence (3-7) into irreducible submodules is

More explicitly, if $\varphi \in \mathcal{V}_{1,2}^{*} \otimes \mathfrak{g}_{1,2}$, then there are elements $r_{i, j}, r_{i, j}^{\prime}, r_{i, j}^{\prime \prime} \in \mathcal{V}_{i, j}$ such that for $p_{1,2} \in \mathcal{V}_{1,2}$,

$$
\begin{align*}
\varphi\left(p_{1,2}\right)= & \left(\left\langle r_{1,2}, p_{1,2}\right\rangle_{1,2}\right)+\left(\left\langle r_{3,2}, p_{1,2}\right\rangle_{1,2}+\left\langle r_{1,2}^{\prime}, p_{1,2}\right\rangle_{0,2}\right)  \tag{3-10}\\
& +\left(\left\langle r_{1,4}, p_{1,2}\right\rangle_{1,2}+\left\langle r_{1,2}^{\prime \prime}, p_{1,2}\right\rangle_{1,1}+\left\langle r_{1,0}, p_{1,2}\right\rangle_{1,0}\right) \in \mathcal{V}_{0,0} \oplus \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}
\end{align*}
$$

Likewise, for any $T \in \Lambda^{2} \mathcal{V}_{1,2}^{*} \otimes \mathcal{V}_{1,2}$, there are elements $s_{i, j}, s_{i, j}^{\prime}, s_{i, j}^{\prime \prime} \in \mathcal{V}_{i, j}$ such that for all $p, q \in \mathcal{V}_{1,2}$,

$$
\begin{align*}
T(p, q)=\left\langle s_{1,2}\right. & \left.,\langle p, q\rangle_{1,0}\right\rangle_{0,2}+\left\langle s_{1,4},\langle p, q\rangle_{1,0}\right\rangle_{0,3}+\left\langle s_{1,6},\langle p, q\rangle_{1,0}\right\rangle_{0,4}  \tag{3-11}\\
& +\left\langle s_{1,0},\langle p, q\rangle_{0,1}\right\rangle_{1,0}+\left\langle s_{1,2}^{\prime},\langle p, q\rangle_{0,1}\right\rangle_{1,1}+\left\langle s_{1,4}^{\prime},\langle p, q\rangle_{0,1}\right\rangle_{1,2} \\
& +\left\langle s_{3,0},\langle p, q\rangle_{0,1}\right\rangle_{2,0}+\left\langle s_{3,2},\langle p, q\rangle_{0,1}\right\rangle_{2,1}+\left\langle s_{3,4},\langle p, q\rangle_{0,1}\right\rangle_{2,2} \\
& +\left\langle s_{1,2}^{\prime \prime},\langle p, q\rangle_{1,2}\right\rangle_{0,0}
\end{align*}
$$

Using the tuple ( $s_{1,2}, s_{1,4}, s_{1,6}, s_{1,0}, s_{1,2}^{\prime}, s_{1,4}^{\prime}, s_{3,0}, s_{3,2}, s_{3,4}, s_{1,2}^{\prime \prime}$ ) as coordinates for $\Lambda^{2} \mathcal{V}_{1,2}^{*} \otimes \mathcal{V}_{1,2}$, another calculation shows that

$$
\begin{gather*}
S p(\varphi)=\left(-\frac{1}{6}\left(r_{1,2}-3 r_{1,2}^{\prime}+4 r_{1,2}^{\prime \prime}\right),-\frac{1}{2} r_{1,4}, 0, r_{1,0},-\frac{1}{8}\left(r_{1,2}+r_{1,2}^{\prime}-4 r_{1,2}^{\prime \prime}\right),\right.  \tag{3-12}\\
\\
\left.-\frac{1}{2} r_{1,4}, 0,-\frac{1}{4} r_{3,2}, 0,-\frac{1}{3}\left(r_{1,2}-3 r_{1,2}^{\prime}-8 r_{1,2}^{\prime \prime}\right)\right),
\end{gather*}
$$

where the $r_{i, j}$ 's are determined by $\varphi$ as in (3-10).
Lemma 3.10. Let $\mathcal{Z}$ be as before, and suppose that $\omega_{1}$ is a special connection on $\mathcal{Z}$. Then another connection $\omega_{2}$ on $\mathcal{Z}$ is special if and only if there are functions $r_{i, j}, r_{i, j}^{\prime}$ on $F$ with values in $\mathcal{V}_{i, j}$ such that

$$
\begin{equation*}
\omega_{2}=\omega_{1}+\left(\left\langle r_{1,2}, \theta\right\rangle_{1,2}\right)+\left(\left\langle r_{3,2}, \theta\right\rangle_{1,2}+\left\langle r_{1,2}^{\prime}, \theta\right\rangle_{0,2}\right)+\left(\left\langle r_{1,0}, \theta\right\rangle_{1,0}\right) . \tag{3-13}
\end{equation*}
$$

Here, we use the identification (3-9) to regard the $\omega_{i}$ 's as $\mathcal{V}_{0,0} \oplus \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$-valued 1 -forms on $F$.
Proof. First of all, we define the vector bundles $\mathcal{V}_{i, j}^{F}:=F \times_{G} \mathcal{V}_{i, j}$ over $\mathcal{Z}$. Recall from $\S 1$ that the difference between two connections on $F \rightarrow \mathcal{Z}$ is determined by a section of the bundle $T^{*} \mathcal{Z} \otimes \mathcal{q}_{F}$. Since by (3-9) we have $\mathfrak{g}_{F} \cong \mathcal{V}_{0,0}^{F} \oplus \mathcal{V}_{2,0}^{F} \oplus \mathcal{V}_{0,2}^{F}$, we can decompose

$$
T^{*} \mathcal{Z} \otimes \mathfrak{g}_{F}=B_{1}^{F} \oplus B_{2}^{F} \quad \text { with } \quad\left\{\begin{array}{c}
B_{1}^{F}:=T^{*} \mathcal{Z} \otimes\left(\mathcal{V}_{0,0}^{F} \oplus \mathcal{V}_{2,0}^{F}\right), \quad \text { and } \\
B_{2}^{F}:=T^{*} \mathcal{Z} \otimes \mathcal{V}_{0,2}^{F}
\end{array}\right.
$$

Note that $B_{2}^{F} \cong \mathcal{V}_{1,2}^{F} \otimes \mathcal{V}_{0,2}^{F} \cong \mathcal{V}_{1,0}^{F} \oplus \mathcal{V}_{1,2}^{F} \oplus \mathcal{V}_{1,4}^{F}$.
Consider the vector bundle

$$
\Delta:=\bigcup_{t \in \mathcal{Z}} H^{0}\left(\operatorname{Hom}\left(N_{C_{t}}, \tau_{C_{t}}\right)\right) \rightarrow \mathcal{Z}
$$

For a fixed $t \in \mathcal{Z}, \operatorname{Hom}\left(N_{C_{t}}, \tau C_{t}\right) \cong \operatorname{Hom}(\mathcal{O}(2) \oplus \mathcal{O}(2), \mathcal{O}(2)) \cong \mathcal{O}(0) \oplus \mathcal{O}(0)$, hence $H^{0}\left(H o m\left(N_{C_{t}}, \tau_{C_{t}}\right)\right) \cong \mathcal{V}_{1,0}$ as a $G$-module, and thus $\Delta \cong \mathcal{V}_{1,0}^{F}$.

Let us fix a special connection $\omega_{0}=\tilde{\omega}+\hat{\sigma}_{0}$ with some section $\sigma_{0}$ of the split bundle $S \rightarrow \mathcal{Z}$. Given a local section $\delta$ of $\Delta$, we let $\omega:=\tilde{\omega}+\hat{\sigma}$ with $\sigma:=\sigma_{0}+\delta$, and define $\psi(\delta):=\omega-\omega_{0}$. From Lemma 2.4. it is easy to verify that $\psi(\delta)$ is a local section of $B_{2}^{F} \subseteq T^{*} \mathcal{Z} \otimes \mathfrak{g}_{F}$, that the correspondence $\delta \mapsto \psi(\delta)$ determines a bundle map $\psi: \Delta \rightarrow B_{2}^{F}$, and that $\psi$ is independent of the choice of $\omega_{0}$. Also, it is obvious that $\psi$ is non-vanishing, hence by Schur's Lemma $\psi(\Delta)=\mathcal{V}_{1,0}^{F} \subseteq B_{2}^{F}$.

Let $\omega_{1}=\tilde{\omega}_{1}+\hat{\sigma}_{1}$ be the decomposition of the special connection $\omega_{1}$ where $\sigma_{1}$ is a section of the split bundle $S$. Then $\omega_{2}$ is special if and only if $\omega_{2}=\tilde{\omega}_{2}+\hat{\sigma}_{2}$ for some section $\sigma_{2}$ of $S$, if and only if $\omega_{2}-\omega_{1}=\left(\tilde{\omega}_{2}-\tilde{\omega}_{1}\right)+\psi(\delta)$ where $\delta:=\sigma_{2}-\sigma_{1}$ is a section of $\Delta$, if and only if $\omega_{2}-\omega_{1}$ is a section of $B_{1}^{F} \oplus \psi(\Delta)=B_{1}^{F} \oplus \mathcal{V}_{1,0}^{F} \subseteq T^{*} \mathcal{Z} \otimes \mathfrak{g}_{F}$.

Comparing (3-13) with (3-10), we see that this is satisfied if and only if (3-13) holds.

Theorem 3.11. Let $\mathcal{Z}$ be the moduli space of rational curves in a 3-fold $\mathcal{W}$ whose normal bundle is equivalent to $\mathcal{O}(2) \oplus \mathcal{O}(2)$, and let $\pi: F \rightarrow \mathcal{Z}$ be the associated $G_{1,2}$-structure. Then there is a unique connection $\omega$ on $F$ and a function $s_{3,0}$ : $F \rightarrow \mathcal{V}_{3,0}$ such that the torsion of $\omega$ is given by

$$
\Theta=\left\langle s_{3,0}(u),\langle\theta, \theta\rangle_{0,1}\right\rangle_{2,0} .
$$

Moreover, $\omega$ is a special connection.
This simple form of the torsion is quite remarkable; indeed, Lemma 3.9. implies that for $k=2, \operatorname{rank}\left(H_{F}^{0,2}\right)=48$. Thus, Theorem 3.11. says that most of the intrinsic torsion of $F$ vanishes.

Proof. First of all, note that it suffices to prove the Theorem locally, i.e. we need to show that $F$ can be covered by open sets $\mathcal{U}_{i}$ on which a connection $\omega_{i}$ with the stated properties exists. Then, by uniqueness, $\omega_{i}$ and $\omega_{j}$ must coincide on $\mathcal{U}_{i} \cap \mathcal{U}_{j}$, thus $\omega_{i}$ is the restriction to $\mathcal{U}_{i}$ of a connection $\omega$ defined on all of $F$. In the proof, we will replace $\mathcal{U}_{i}$ by $\mathcal{Z}$ and thus we may assume that all local properties of $\mathcal{Z}$ hold globally.

By Proposition 2.6. we can find a special connection $\omega_{0}$ on $F$. Then there are functions $\left(s_{1,2}, s_{1,4}, \ldots, s_{1,2}^{\prime \prime}\right)$ on $F$ with values in $\mathcal{V}_{1,2}, \mathcal{V}_{1,4}, \ldots, \mathcal{V}_{1,2}$ respectively such that the torsion $\Theta_{0}$ of $\omega_{0}$ is given by $\Theta_{0}\left(\xi, \xi^{\prime}\right)=T_{0}(p, q)$ with $p=\theta(\xi), q=$ $\theta\left(\xi^{\prime}\right)$, and where $T_{0}(p, q)$ is determined by the $s_{i, j}$ 's as in (3-11).

We call $T_{0}: F \rightarrow \Lambda^{2} \mathcal{V}_{1,2}^{*} \otimes \mathcal{V}_{1,2}$ the torsion map of $\omega_{0}$. By abuse of notation, we write $T_{0}=s_{1,2}+s_{1,4}+\ldots+s_{1,2}^{\prime \prime}$.

We shall say that $r \in \mathcal{V}_{1}$ divides $p \in \mathcal{V}_{1, k}$ and write $r \mid p$ if $p=x \otimes p_{1}+y \otimes p_{2}$ and $r$ divides both $p_{1}$ and $p_{2}$. From Corollary 2.8. we obtain the following criterion:
(3-14) If for $r \in \mathcal{V}_{1}$ and $p, q \in \mathcal{V}_{1,2}$ we have $r \mid p$ and $r \mid q$ then also $r \mid T_{0}(u)(p, q)$.
From (3-14), we can conclude that some of the $s_{i, j}$ 's must vanish identically. For example, let $p:=x \otimes r^{2}$ and $q:=y \otimes r^{2}$ for $r \in \mathcal{V}_{1}$. Then $\langle p, q\rangle_{0,1}=\langle p, q\rangle_{1,2}=0$ and $\langle p, q\rangle_{1,0}=1 \otimes r^{4} \in \mathcal{V}_{0,4}$. Since $r \mid p$ and $r \mid q$,(3-14) implies that $r \mid T_{0}(u)(p, q)$. An easy computation shows that this is the case if and only if $r \mid s_{1,6}(u)$. But this must be true for all $r \in \mathcal{V}_{1}$ and $u \in F$, thus we conchude $s_{1,6}=0$.

By similar calculations we see that (3-14) is satisfied if and only if

$$
\begin{equation*}
s_{1,4}=s_{1,4}^{\prime}=s_{1,6}=s_{3,4}=s_{1,2}^{\prime \prime}-2 s_{1,2}=0 \tag{3-15}
\end{equation*}
$$

From here it follows that the intrinsic torsion of the $G_{1,2}$-structure is represented by $s_{3,0}$. Also, from (3-12) and (3-15) it follows that $T_{0}-s_{3,0}=S p(\varphi)$ for some function $\varphi: F \rightarrow \mathcal{V}_{1,2}^{*} \otimes g_{1,2}$ whose $r_{1,4}$ and $r_{1,2}^{\prime \prime}$ component vanish. Then Lemma 3.10. implies that the connection $\omega:=\omega_{0}-\varphi$ is still special, and if we let $T$ be the torsion map of $\omega$ then by ( $1-7$ ) we have $T=T_{0}-S p(\varphi)=s_{0,3}$. Thus, the torsion of the special connection $\omega$ is of the desired form.

The uniqueness follows from Proposition 1.2. together with Lemma 3.9.

Definition 3.12. The unique special connection from Theorem 3.11. is called the intrinsic connection of $\mathcal{Z}$.

Theorem 3.13. Let $\mathcal{W}$ be a contact 3-fold with contact line bundle $L \rightarrow \mathcal{W}$, and let $\mathcal{Y}$ be the moduli space of rational contact curves $C$ such that $\left.L\right|_{C} \cong \mathcal{O}(-3)$. Then there is a unique torsion free connection $\hat{\omega}$ on the $G_{3}-$ structure $\pi y: \hat{F} \rightarrow \mathcal{Y}$. Moreover, $\hat{\omega}$ is special.

Proof. By Proposition 3.1. $\mathcal{Y} \subseteq \mathcal{Z}$ is a submanifold with $\mathcal{Z}$ as in Theorem 3.11. Let $\omega_{0}$ be the intrinsic connection on $\mathcal{Z}$, and let $s_{3}: F \rightarrow \mathcal{V}_{3}$ be such that $s_{3} \otimes 1$ : $F \rightarrow \mathcal{V}_{3,0}$ is the torsion function of $\omega_{0}$ from Theorem 3.11.

Let $s_{1,2}:=x \otimes\left(s_{3}\right)_{x}+y \otimes\left(s_{3}\right)_{y} \in \mathcal{V}_{1,2}$, and let $\varphi: F \rightarrow \mathcal{V}_{1,2}^{*} \otimes \mathfrak{g}_{1,2}$ be determined by (3-10) with $r_{1,2}=r_{1,2}^{\prime}:=2 s_{1,2}$, all other $r_{i, j}$ 's $=0$. As before, $\varphi$ can be regarded as a section of $T^{*} \mathcal{Z} \otimes g_{F}$, and by Lemma 3.10, the connection $\omega:=\omega_{0}+\varphi$ is again a special connection on $\mathcal{Z}$. We denote by $\hat{\omega}$ the restriction of $\omega$ to $\mathcal{Y}$, and let $\Theta, \Theta_{0}$ and $\hat{\Theta}$ denote the torsion forms of $\omega, \omega_{0}$ and $\hat{\omega}$ respectively. By (1-7), $\Theta=\Theta_{0}+S p(\varphi)$.

Then by Proposition 3.7. and some calculation we have

$$
\begin{aligned}
\hat{\Theta} & =\underline{p r} \circ \Theta \\
& =\underline{p r}\binom{\left\langle s_{3,0},\langle\theta, \theta\rangle_{0,1}\right\rangle_{2,0}-\frac{1}{2}\left\langle s_{1,2},\langle\theta, \theta\rangle_{0,1}\right\rangle_{1,1}}{\quad+\frac{2}{3}\left\langle s_{1,2},\langle\theta, \theta\rangle_{1,0}\right\rangle_{0,2}+\frac{4}{3}\left\langle s_{1,2},\langle\theta, \theta\rangle_{1,2}\right\rangle_{0,0}} \\
& =0
\end{aligned}
$$

Thus, $\hat{\omega}$ is the desired torsion free special connection. The uniqueness follows from Proposition 1.2. together with Lemma 3.9.

## $\S 4$ Torsion free $G_{1,2}$-structures.

In this entire section, we shall consider complex sixfolds $\mathcal{Z}$ which carry a torsion free $G_{1,2}$-structure $\pi: F \rightarrow \mathcal{Z}$. In this case, there is a unique torsion free connection $\omega=\omega_{0,0}+\omega_{2,0}+\omega_{0,2}$ on $F$ where $\omega_{i, j}$ takes values in $\mathcal{V}_{i, j}$. Here, we used the identification $\mathfrak{g}_{1,2} \cong \mathcal{V}_{0,0} \oplus \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$ from (3-9).

For convenience, we shall define the pairings

$$
\begin{aligned}
& \langle\langle-,-\rangle\rangle^{(k)}:\left(\mathcal{V}_{0,0} \oplus \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}\right) \otimes \mathcal{V}_{i, j} \rightarrow \quad \mathcal{V}_{i, j} \\
& \left\langle\left\langle p_{0,0}+p_{2,0}+p_{0,2}, q\right\rangle\right\rangle^{(k)}:=k\left\langle p_{0,0}, q\right\rangle_{0,0}+\left\langle p_{2,0}, q\right\rangle_{1,0}+\left\langle p_{0,2}, q\right\rangle_{0,1}
\end{aligned}
$$

Then the first structure equation of $\omega$ reads

$$
\begin{equation*}
d \theta+\langle\langle\omega, \theta\rangle\rangle^{(1)}=0 \tag{4-1}
\end{equation*}
$$

with the $\mathcal{V}_{1,2}$-valued tautological 1-form $\theta$.
Moreover, the curvature 2-form $\Omega$ takes values in $\mathfrak{g}_{1,2} \cong \mathcal{V}_{0,0} \oplus \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$, and is defined as

$$
\begin{align*}
\Omega & =d \omega+\omega \wedge \omega \\
& =d \omega-\frac{1}{2}\left(\left\langle\omega_{2,0}, \omega_{2,0}\right\rangle_{1,0}+\left\langle\omega_{0,2}, \omega_{0,2}\right\rangle_{0,1}\right) . \tag{4-2}
\end{align*}
$$

Differentiating (4-1), we obtain the first Bianchi identity

$$
\begin{equation*}
\langle\langle\Omega, \theta\rangle\rangle^{(1)}=0 \tag{4-3}
\end{equation*}
$$

Let $\mathbf{K}\left(\mathfrak{g}_{1,2}\right)$ be given by the exact sequence

$$
0 \longrightarrow \mathrm{~K}\left(\mathfrak{g}_{1,2}\right) \longrightarrow \Lambda^{2} \mathcal{V}_{1,2}^{*} \otimes \mathfrak{g}_{1,2} \xrightarrow{S_{P}} \Lambda^{3} \mathcal{V}_{1,2}^{*} \otimes \mathcal{V}_{1,2}
$$

where $S p_{2}$ is given by skew-symmetrization of $\Lambda^{2} \mathcal{V}_{1,2} \otimes g_{1,2} \subseteq \Lambda^{2} \mathcal{V}_{1,2} \otimes\left(\mathcal{V}_{1,2}^{*} \otimes \mathcal{V}_{1,2}\right)$. The first Bianchi identity (4-3) can be interpreted as stating that $\Omega$ is a section of $F \times_{G} \mathbf{K}\left(\mathfrak{g}_{1,2}\right)$.

A calculation shows that, as a $G$-module, $K\left(g_{1,2}\right) \cong \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$. More explicitly, there is a function $\mathbf{a}=a_{2,0}+a_{0,2}: F \rightarrow \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$ such that

$$
\begin{align*}
\Omega=( & \left.-4\left\langle a_{2,0},\langle\theta, \theta\rangle_{1,2}\right\rangle_{0,0}+3\left\langle a_{0,2},\langle\theta, \theta\rangle_{0,1}\right\rangle_{0,2}\right) \\
& +\left(\left\langle a_{2,0},\langle\theta, \theta\rangle_{0,1}\right\rangle_{2,0}+\left\langle a_{0,2},\langle\theta, \theta\rangle_{1,0}\right\rangle_{0,2}-7\left\langle a_{0,2},\langle\theta, \theta\rangle_{1,2}\right\rangle_{0,0}\right) \tag{4-4}
\end{align*}
$$

This implies, in particular, that $d \omega_{0,0}=0$. Therefore, by the Ambrose-SingerHolonomy Theorem [KN], the holonomy of $\omega$ is contained in the subgroup

$$
H_{1,2}:=G_{1,2} \cap S l\left(V_{1,2}\right) .
$$

Taking the derivative of (4-4) and solving for $d \mathbf{a}$, we see that there is a function b: $F \rightarrow \mathcal{V}_{1,2}$ such that

$$
\begin{equation*}
d \mathbf{a}=\langle\langle\omega, \mathbf{a}\rangle\rangle^{(-2)}+3\langle\mathbf{b}, \theta\rangle_{0,2}+\langle\mathbf{b}, \theta\rangle_{1,1} . \tag{4-5}
\end{equation*}
$$

Once again, we take the derivative of (4-5) and solve for $d \mathbf{b}$. We see that there is a function $c: F \rightarrow V_{0,0}$ such that

$$
\begin{align*}
& d \mathbf{b}=\langle\langle\mathbf{b}, \omega\rangle\rangle^{(-3)}+2\left\langle\left\langle a_{2,0}, a_{0,2}\right\rangle_{0,0}, \theta\right\rangle_{1,1}+\left\langle\left\langle a_{0,2}, a_{0,2}\right\rangle_{0,0}, \theta\right\rangle_{0,2} \\
&+\left\langle-\frac{4}{3}\left\langle a_{2,0}, a_{2,0}\right\rangle_{2,0}-7\left\langle a_{0,2}, a_{0,2}\right\rangle_{0,2}+c, \theta\right\rangle_{0,0} \tag{4-6}
\end{align*}
$$

Taking exterior derivatives one more time and solving for $d c$ we calculate that

$$
\begin{equation*}
d c=-4 c \omega_{0,0} \tag{4-7}
\end{equation*}
$$

The reader who is familiar with $[\mathrm{Br}]$ will note the similarity of the structure equations (4-1) - (4-7) with the structure equations for $H_{3}$-connections where $H_{3}=$ $G_{3} \cap \operatorname{Sl}\left(\mathcal{V}_{3}\right)$. This is by no means a coincidence. As we shall see in the following section, there is a close relationship between $H_{1,2}$-structures and $H_{3}$-structures.

Let $F_{0} \subseteq F$ be an integral hypersurface of $\omega_{0,0}$, i.e. a hypersurface such that $\left.\omega_{0,0}\right|_{F_{0}} \equiv 0$. Then $F_{0}$ is a torsion free $H_{1,2}$-reduction of $F$. We shall denote the restrictions of $\theta, \omega_{2,0}, \omega_{0,2}, \mathbf{a}$ and $\mathbf{b}$ to $F_{0}$ by the same letters. Note that $\omega_{0}:=\left.\omega\right|_{F_{0}}=\omega_{2,0}+\omega_{0,2}$ is $\mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$-valued. Also, by (4-7), $c$ is constant on $F_{0}$.

Definition 4.1. Let $\pi: F \rightarrow \mathcal{Z}$ be a torsion free $G_{1,2}$-structure and let $F_{0} \subseteq F$ be an integral hypersurface of $\omega_{0,0}$. Then $F_{0}$ is called an associated $H_{1,2}-$ structure of $F$.

The choice of associated $H_{1,2}$-structures is, of course, not unique. However, given two such structures $F_{0}$ and $F_{0}^{\prime}$ then $F_{0}^{\prime}=R_{t I} \cdot F_{0}$ for some $t \in \mathbb{C}^{*}$. Hence, to each torsion free $G_{1,2}$-structure there is a one parameter family of associated $H_{1,2}$-structures.

Our approach to solve the structure equations (4-1) - (4-7) will be motivated by the steps pursued in $[\mathrm{Br}]$ to solve the structure equations of an $H_{3}$-connection.

Let

$$
K:=\mathbf{a}+\mathrm{b}: F_{0} \rightarrow \mathcal{V}, \quad \text { where } \quad \mathcal{V}=\mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2} \oplus \mathcal{V}_{1,2}
$$

Equations (4-5) - (4-6) can be summarized as

$$
d I \zeta=J\left(\theta+\omega_{0}\right)
$$

where $J$ is a function on $F$ with values in $\operatorname{Hom}(\mathcal{V}, \mathcal{V})$. Now $J=K^{*}\left(\mathbf{J}_{c}\right)$ where $\mathrm{J}_{c}: \mathcal{V} \rightarrow \operatorname{Hom}(\mathcal{V}, \mathcal{V})$ is a polynomial mapping which depends upon a parameter $c$. If we write $\mathbf{J}_{\boldsymbol{c}}$ relative to the standard basis of $\mathcal{V}$ then it has a $12 \times 12$-matrix representation whose entries are polynomials in the components of $\mathbf{a}$ and $\mathbf{b}$.

It turns out that this matrix $\mathbf{J}_{c}$ is not invertible. In fact, generically the rank of $\mathbf{J}_{c}$ is calculated to be 10. This implies that the image of $K$ is contained in some 10 -dimensional subvariety of $\mathcal{V}$.

Let us this once comment on the mechanical calculations which are performed to arrive at this conclusion. The attempt of simply taking the determinant of $\mathbf{J}_{c}$ on MATHEMATICA failed miserably at first: after more than 10 minutes of calculation, memory overflows occured.

The next approach was to use the $H_{1,2}$-equivariance of $\mathbf{J}_{c}$. Under the generic assumption that both $a_{2,0}$ and $a_{0,2}$ are not squares of a linear polynomial, we may assume that $a_{2,0}=t x y \otimes 1$ and $a_{0,2}=t^{\prime} x y \otimes 1$ for some $t, t^{\prime} \in \mathbb{C}$. Making this replacement simplifies $\mathbf{J}_{c}$ to a matrix $\mathbf{J}_{c}^{\prime}$ of equal rank which is drastically simpler, and calculating that $\operatorname{det}\left(\mathbf{J}_{c}^{\prime}\right)=0$ on MATHEMATICA is a matter of less than a minute.

Moreover, we can explicitly compute the kernel of $\mathbf{J}_{c}^{\prime}$, and thus by equivariance the kernel of $\mathbf{J}_{c}$. The result can be described as follows. Let

$$
\begin{aligned}
d_{1} \otimes 1 & :=\begin{array}{ll}
\left\langle a_{2,0}, a_{2,0}\right\rangle_{2,0} & e_{1} \otimes 1:=\left\langle\left\langle a_{2,0}, \mathbf{b}\right\rangle_{1,0}, \mathbf{b}\right\rangle_{1,2} \\
d_{2} \otimes 1 & :=\left\langle a_{0,2}, a_{0,2}\right\rangle_{0,2}
\end{array} \quad e_{2} \otimes 1:=\left\langle\left\langle a_{0,2}, \mathbf{b}\right\rangle_{0,1}, \mathbf{b}\right\rangle_{1,2} \\
b_{2,0} & :=\langle\mathbf{b}, \mathbf{b}\rangle_{1,1} \\
b_{2,4} & :=\langle\mathbf{b}, \mathbf{b}\rangle_{0,2} \\
p_{2,0} & \left.=\left\langle a_{2,0}, a_{0,2}\right\rangle_{0,0}, a_{0,2}\right\rangle_{0,0} \\
p_{2,4} & :=\left\langle\left\langle a_{2,0}, a_{2,0}\right\rangle_{0,0}, a_{2,0}\right\rangle_{2,0} \\
p_{0,2} & :=10\left\langle\left\langle a_{2,0}, a_{0,2}\right\rangle_{0,0}, a_{2,0}\right\rangle_{2,0}+9\left\langle\left\langle a_{0,2}, a_{0,2}\right\rangle_{0,0}, a_{0,2}\right\rangle_{0,2} \\
& \quad-12 c a_{0,2}+3 b_{0,2}
\end{aligned}
$$

Here, $d_{i}$ and $e_{i}$ are $\mathbb{C}$-valued functions on $\mathcal{V}$, while $b_{i, j}$ and $p_{i, j}$ are functions on $\mathcal{V}$ with values in $\mathcal{V}_{i, j}$. Then we have the

## Proposition 4.2. Let

$$
f_{1}^{c}:=\left(4 d_{1}-9 d_{2}\right)\left(4 d_{1}+27 d_{2}-6 c\right)+72 e_{1}-54 e_{2}
$$

and

$$
f_{2}^{c}:=4 d_{2}\left(4 d_{1}+9 d_{2}-3 c\right)^{2}+96\left\langle p_{2,0}, b_{2,0}\right\rangle_{2,0}+3\left\langle p_{0,2}, b_{0,2}\right\rangle_{0,2}+48\left\langle p_{2,4}, b_{2,4}\right\rangle_{2,4} .
$$

Then $d\left(K \circ f_{i}^{c}\right)=0$ for $i=1,2$, and hence $K$ maps $F_{0}$ into a level set of $\left(f_{1}^{c}, f_{2}^{c}\right)$. Moreover, $\operatorname{rank}\left(\mathbf{J}_{c}\right)=10$ at $x \in \mathcal{V}$ if and only if $\left.d f_{1}^{c} \wedge d f_{2}^{c}\right|_{x} \neq 0$.
Proof. The calculations involved to verify this Proposition were all performed on mathematica and will not be presented here in further detail.

We let

$$
\Sigma_{c}:=\left\{x \in \mathcal{V}\left|d f_{1}^{c} \wedge d f_{2}^{c}\right|_{x}=0\right\}
$$

Then by Proposition 4.2. we know that $\operatorname{rank}(K)_{u}=10$ at $u \in F_{0}$ if and only if $K(u) \notin \Sigma_{c}$.

Let us define the functions $r_{i, j}^{k}: \mathcal{V} \rightarrow \mathcal{V}_{i, j}$ for $k=1,2$ by the equation

$$
d f_{k}^{c}=\frac{1}{6}\left\langle r_{2,0}^{k}, d a_{2,0}\right\rangle_{2,0}+\frac{1}{2}\left\langle r_{0,2}^{k}, d a_{0,2}\right\rangle_{0,2}+\frac{1}{2}\left\langle r_{1,2}^{k}, d \mathbf{b}\right\rangle_{1,2} \quad \text { for } k=1,2,
$$

and define the vector fields $Z_{k}, k=1,2$, on $F_{0}$ by

$$
\omega_{0}\left(Z_{k}\right)=r_{2,0}^{k}+r_{0,2}^{k} \quad \text { and } \quad \theta\left(Z_{k}\right)=r_{1,2}^{k} .
$$

Then another MATHEMATICA calculation yields
Proposition 4.3. The vector fileds $Z_{1}$ and $Z_{2}$ on $F_{0}$ defined above are symmetries, i.e. their Lie derivatives satisfy

$$
\begin{equation*}
\mathfrak{L}_{Z_{k}}\left(\omega_{0}\right)=\omega_{0} \quad \text { and } \quad \mathfrak{L}_{Z_{k}}(\theta)=\theta \quad \text { for } k=1,2 \tag{4-8}
\end{equation*}
$$

Moreover, $\left[Z_{1}, Z_{2}\right]=0$.
Corollary 4.4. Either $\operatorname{rank}(K) \equiv 10$ or $\operatorname{rank}(K)<10$ on all of $F_{0}$.
Proof. From (4-8), standard arguments show that a symmetry either vanishes everywhere or nowhere on $F_{0}$. Thus, either $Z_{1}$ and $Z_{2}$ are pointwise linearly independent everywhere or nowhere on $F_{0}$.

From the definitions of the $Z_{k}$ 's it follows that $Z_{1}$ and $Z_{2}$ are linearly independent if and only if $d f_{1}^{c}$ and $d f_{2}^{c}$ are linearly independent. The claim follows then from Proposition 4.2.
Definition 4.5. A torsion free $H_{1,2}$-connection is called regular if $\operatorname{rank}(K) \equiv 10$, with the map $K: F_{0} \rightarrow \mathcal{V}$ from above.

A torsion free $G_{1,2}$-connection is called regular if one and hence all of its associated $H_{1,2}$-structures are regular.

Thus, for a regular $H_{1,2}$-connection, the map $K$ is a submersion onto an open subset of the regular part of a level set of $\left(f_{1}^{c}, f_{2}^{c}\right)$ in $\mathcal{V}$.

Definition 4.6. Given constants $c, c_{1}, c_{2} \in \mathbb{C}$ let

$$
\mathcal{C}\left(c, c_{1}, c_{2}\right):=\left(f_{1}^{c}, f_{2}^{c}\right)^{-1}\left(c_{1}, c_{2}\right) \backslash \Sigma_{c} \subseteq \mathcal{V}
$$

If for a regular torsion free $H_{1,2}$-connection on $\pi: F_{0} \rightarrow \mathcal{Z}$ the image of $K: F_{0} \rightarrow$ $\mathcal{V}$ is contained in $\mathcal{C}_{c, c_{1}, c_{2}}$ then we call the triple $\left(c, c_{1}, c_{2}\right)$ the structure constants of the connection.

Let us now consider the question of existence of torsion free $H_{1,2}$-connections.
Theorem 4.7. Given constants $c, c_{1}, c_{2} \in \mathbb{C}$ let $\mathcal{C}:=\mathcal{C}\left(c, c_{1}, c_{2}\right) \subseteq \mathcal{V}$. Then $\mathcal{C}$ can be covered by open sets $U$ which have the following property: there exists a holomorphic principal $\mathbb{C}^{2}$-bundle $K: F_{0} \rightarrow U$ over $U$ and holomorphic 1 -forms $\theta$ and $\omega_{0}$ on $F_{0}$ with values in $\mathcal{V}_{1,2}$ and $\mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$ respectively satisfying
(1) the $\mathcal{V}_{1,2} \oplus \mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$-valued 1-form $\theta+\omega_{0}$ is a coframe on $F_{0}$,
(2) equations (4-1) - (4-7) are satisfied if we set $\omega_{0,0}=0$, and if $K=\mathbf{a}+\mathbf{b}$ is the decomposition of $K$ into its $\mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$ and $\mathcal{V}_{1,2}$ components respectively.
Moreover, the triple $\left(F_{0}, \theta, \omega_{0}\right)$ is unique in the sense that if $\left(F_{0}^{\prime}, \theta^{\prime}, \omega_{0}^{\prime}\right)$ is another triple satisfying (1) and (2), then there is a bundle isomorphism between $F_{0}$ and $F_{0}^{\prime}$ which identifies the coframings.

Proof. Let $\bar{a}, \bar{b}, \bar{r}_{i, j}^{k}$ and $\bar{J}$ be the restrictions of the functions $\mathbf{a}, \mathbf{b}, r_{i, j}^{k}$ and $\mathbf{J}_{c}$ respectively to $\mathcal{C}$.

By definition of $\mathcal{C}$ we have $\operatorname{rank}(\bar{J}) \equiv 10$. From here it follows that there exist smooth 1-forms $\bar{\theta}$ and $\bar{\omega}_{0}$ on $\mathcal{C}$ with values in $\mathcal{V}_{1,2}$ and $\mathcal{V}_{2,0} \oplus \mathcal{V}_{0,2}$ respectively such that

$$
\begin{equation*}
d \bar{a}+d \bar{b}=\bar{J}\left(\bar{\theta}+\bar{\omega}_{0}\right) . \tag{4-9}
\end{equation*}
$$

Since $d \bar{a}, d \bar{b}$ and $\bar{J}$ are holomorphic, we may assume that $\bar{\theta}$ and $\bar{\omega}_{0}$ are of type $(1,0)$.

The kernel of $\bar{J}$ is spanned at each point by the vectors $\bar{r}_{2,0}^{k}+\bar{r}_{0,2}^{k}+\bar{r}_{1,2}^{k}$ for $k=1,2$, so once one solution $\left(\bar{\theta}, \bar{\omega}_{0}\right)$ to (4-9) has been found, any other can be written in the form $\left(\bar{\theta}+\sum_{k} \bar{r}_{1,2}^{k} \alpha_{k}, \bar{\omega}_{0}+\sum_{k}\left(\bar{r}_{2,0}^{k}+\bar{r}_{0,2}^{k}\right) \alpha_{k}\right)$ for unique 1 -forms $\alpha_{k}$, $k=1,2$.

Now we define the 2 -forms

$$
\begin{align*}
& \bar{\Theta}=d \bar{\theta}+\left\langle\left\langle\bar{\omega}_{0}, \bar{\theta}\right\rangle\right\rangle^{(1)} \\
& \bar{\Phi}=d \bar{\omega}_{0}-\frac{1}{2}\left(\left\langle\bar{\omega}_{2,0}, \bar{\omega}_{2,0}\right\rangle_{1,0}+\left\langle\bar{\omega}_{0,2}, \bar{\omega}_{0,2}\right\rangle_{0,1}\right)-\bar{\Omega} \tag{4-10}
\end{align*}
$$

where $\bar{\Omega}$ is given by replacing $a_{i, j}$ and $\theta$ by $\bar{a}_{i, j}$ and $\bar{\theta}$ respectively in (4-4).
After some calculation, the exterior derivative of (4-9) can be written in the form

$$
0=\bar{J}(\bar{\Theta}+\bar{\Phi})
$$

This implies that there are 2 -forms $\bar{\Psi}_{1}$ and $\bar{\Psi}_{2}$ such that

$$
\begin{equation*}
\bar{\Theta}=\sum_{k} \bar{r}_{1,2}^{k} \bar{\Psi}_{k}, \quad \text { and } \quad \bar{\Phi}=\sum_{k}\left(\bar{r}_{2,0}^{k}+\bar{r}_{0,2}^{k}\right) \bar{\Psi}_{k} \tag{4-11}
\end{equation*}
$$

Substituting these relations into (4-10) and differentiating, we compute that

$$
0=\sum_{k} \bar{r}_{1,2}^{k} d \bar{\Psi}_{k}, \quad \text { and } \quad 0=\sum_{k}\left(\bar{r}_{2,0}^{k}+\bar{r}_{0,2}^{k}\right) d \bar{\Psi}_{k}
$$

Since the functions $\bar{r}_{1,2}^{k}+\bar{r}_{2,0}^{k}+\bar{r}_{0,2}^{k}$ are linearly independent, we conclude that

$$
d \bar{\Psi}_{k}=0 \text { for } k=1,2 .
$$

Let $U \subset \mathcal{C}$ be an open set on which the $\bar{\Psi}_{k}$ 's are exact. Clearly, $\mathcal{C}$ can be covered by such open sets. Let $\alpha_{k}$ be 1 -forms on $U$ such that $d \alpha_{k}=\bar{\Psi}_{k}$. If we replace the pair $\left(\bar{\theta}, \vec{\omega}_{0}\right)$ by $\left(\bar{\theta}-\sum_{k} \bar{r}_{1,2}^{k} \alpha_{k}, \bar{\omega}_{0}-\sum_{k}\left(\bar{r}_{2,0}^{k}+\bar{r}_{0,2}^{k}\right) \alpha_{k}\right)$, then another calculation shows that for this new pair

$$
\begin{align*}
& 0=d \bar{\theta}+\left\langle\left\langle\bar{\omega}_{0}, \bar{\theta}\right\rangle\right\rangle^{(1)} \\
& 0=d \bar{\omega}_{0}-\frac{1}{2}\left(\left\langle\bar{\omega}_{2,0}, \bar{\omega}_{2,0}\right\rangle_{1,0}+\left\langle\bar{\omega}_{0,2}, \bar{\omega}_{0,2}\right\rangle_{0,1}\right)-\bar{\Omega} \tag{4-12}
\end{align*}
$$

Note that from (4-10) and (4-11) it follows that $\bar{\Psi}_{k}$ has no (0,2)-part. Thus, $\alpha_{k}$ can be chosen to be of type ( 1,0 ). But then (4-12) implies that $\bar{\theta}$ and $\bar{\omega}_{0}$ are holomorphic 1 -forms.

Now we let $F_{0}:=U \times \mathbb{C}^{2}$ with coordinates $\left(\bar{a}, \bar{b}, s_{1}, s_{2}\right)$ and define the 1 -forms

$$
\left(\theta, \omega_{0}\right):=\left(\bar{\theta}+\sum_{k} \bar{r}_{1,2}^{k} d s_{k}, \bar{\omega}_{0}+\sum_{k}\left(\bar{r}_{2,0}^{k}+\bar{r}_{0,2}^{k}\right) d s_{k}\right) .
$$

Then it is not hard to show that $\left(\theta, \omega_{0}\right)$ is a holomorphic coframe on $F_{0}$ satisfying the postulates of the Theorem.

The uniqueness of $\left(\theta, \omega_{0}\right)$ follows from the standard facts about mappings preserving coframings [G].

We are now ready to prove the existence result for $H_{1,2}$-connections.
Corollary 4.8. For any constants $c, c_{1}, c_{2} \in \mathbb{C}$ and any point $u \in \mathcal{C}\left(c, c_{1}, c_{2}\right)$, there exists a regular torsion free connection on some $H_{1,2}$-structure $\pi: F_{0} \rightarrow \mathcal{Z}$ where $\mathcal{Z}$ is some sixfold so that the image of the curvature map $K: F_{0} \rightarrow \mathcal{C}_{c_{1}, c_{1}, c_{2}}$ contains $u$.

Proof. Let $U \subseteq \mathcal{C}_{c, c_{1}, c_{2}}$ be an open neighborhood of $u$ for which the conclusion of Theorem 4.7. holds, i.e. there is a principal $\mathbb{C}^{2}$-bundle $K: \tilde{F}_{0} \rightarrow U$ and a coframe $(\tilde{\theta}, \tilde{\omega})$ on $\tilde{F}_{0}$ satisfying (4-1) - (4-7) with $\omega_{0,0}=0$.

Pick a point $v \in \tilde{F}_{0}$ with $K(v)=u$. Since by the structure equations we have $d \tilde{\theta} \equiv 0 \bmod \tilde{\theta}$, it follows that $\tilde{F}_{0}$ is foliated by integral leafs on which $\tilde{\theta}$ vanishes. For some sufficiently small neighborhood $V$ of $v$, there exists a submersion $\pi: V \rightarrow \mathcal{Z}$ onto some sixfold $\mathcal{Z}$ such that $\operatorname{ker}\left(\pi_{*}\right)=\tilde{\theta}^{\perp}$.

Moreover, standard arguments show that there is an inclusion z: $V \hookrightarrow F_{0} \subseteq \mathfrak{F}$ of $V$ into an $H_{1,2}$-structure $F_{0}$ on $\mathcal{Z}$ such that $\imath^{*}(\theta)=\tilde{\theta}$ where $\theta$ denotes the tautological form on $F_{0}$.

Also, there is an unique $H_{1,2}$-connection $\omega_{0}$ on $F_{0}$ with $\imath^{*}\left(\omega_{0}\right)=\dot{\omega}_{0}$. From the structure equations it is then eviclent that the curvature map $K: F_{0} \rightarrow \mathcal{V}$ satisfies $u \in K\left(F_{0}\right) \subseteq \mathcal{C}_{c, c_{1}, c_{2}}$.

As a consequence of the proof of Theorem 4.7. we have

Corollary 4.9. All regular torsion free $H_{1,2}$ - and $G_{1,2}$-connections are holomorphic.

## §5 Summary.

In $\S 3$ we have shown that the moduli space $\mathcal{Z}$ of rational curves $C$ in a complex threefold $\mathcal{W}$ whose normal bundle $N_{C} \rightarrow C$ is equivalent to $\mathcal{O}(2) \oplus \mathcal{O}(2)$ forms a six dimensional manifold which carries a natural $G_{1,2}$-structure $\pi: F \rightarrow \mathcal{Z}$. By Theorem 3.11. most of the intrinsic torsion of this structure vanishes. A natural question is whether every holomorphic $G_{1,2}$-structure whose torsion is of the form of Theorem 3.11. arises from such a moduli space.

The answer is negative in general. The reason is that Proposition 2.9. gives some first order restriction which is not automatically satisfied if the torsion is of the form of Theorem 3.11., not even when the torsion vanishes.

Before stating this result, let us write out the decompositions

$$
\begin{aligned}
\theta=\begin{array}{cc}
\theta_{1,2} & x \otimes x^{2}+\theta_{1,0} \\
& x \otimes x y+\theta_{1,-2} x \otimes y^{2} \\
\theta_{-1,2} & y \otimes x^{2}+\theta_{-1,0} \\
y \otimes x y & +\theta_{-1,-2} y \otimes y^{2}
\end{array}
\end{aligned}
$$

and

$$
\begin{aligned}
& \omega= \omega_{0,0} 1 \otimes 1 \\
&+\omega_{0,2}^{02} 1 \otimes x^{2}+\omega_{0,0}^{02} 1 \otimes x y+\omega_{0,-2}^{02} \\
&+\omega_{2,0}^{20} x^{2} \otimes 1+y^{2} \\
&+\omega_{0,0}^{20} x y \otimes 1+\omega_{-2,0}^{20} \\
& y^{2} \otimes 1 .
\end{aligned}
$$

Proposition 5.1. Suppose $\mathcal{Z}$ is the moduli space of rational curves in the threefold $\mathcal{W}$ whose normal bundle is equivalent to $\mathcal{O}(2) \oplus \mathcal{O}(2)$, and suppose furthermore that the associated $G_{1,2}$-structure $\pi: F \rightarrow \mathcal{Z}$ is torsion free. Then the torsion free connection on $F$ is locally symmetric.

Proof. By Theorem 3.11. the torsion free connection on $\pi: F \rightarrow \mathcal{Z}$ must be special. Thus, by Proposition 2.9.,

$$
\mathcal{I}:=\operatorname{ker}\left(p r_{1} \circ \pi_{F, \mathcal{N}}\right)_{*}=\left\{\theta_{1,-2}, \theta_{-1,-2}, \omega_{0,-2}^{02}\right\}
$$

Of course, this means that $\mathcal{I}$ must satisfy the Frobenius condition $d \mathcal{I} \equiv 0 \bmod \mathcal{I}$. However, from the structure equations (4-1) - (4-4) we compute that $d \omega_{0,-2}^{02} \equiv$ $9\left\langle a_{0,2}, x^{2}\right\rangle_{2} \theta_{1,0} \wedge \theta_{-1,0} \bmod \mathcal{I}$. From here it follows that the Frobenius condition is satisfied if and only if $a_{0,2} \equiv 0$ on $F$. By (4-5) and (4-6), this implies that $\mathbf{b} \equiv 0$ and $\left\langle a_{2,0}, a_{2,0}\right\rangle_{2,0}=\frac{3}{4} c$.

However, $\mathbf{b}$ represents the covariant derivative of the curvature tensor. It follows that $F$ is locally symmetric.

Let us now consider the question which regular torsion free $G_{1,2}$-connections $(\pi: F \rightarrow \mathcal{Z}, \theta, \omega)$ admit a restriction $(\pi: \hat{F} \rightarrow \mathcal{Y}, \hat{\theta}, \hat{\omega})$ in the sense of Definition 3.6. Since the holonomy of a torsion free $G_{1,2}$-connection is contained in $H_{1,2}$ it follows that the holonomy of the restriction to $\mathcal{Y}$ is contained in $H_{3}$.

Proposition 5.2. Let $(\theta, \omega)$ be a regular torsion free $H_{1,2}$-connection on $\pi: F_{0} \rightarrow$ $\mathcal{Z}$ with structure constants $\left(c, c_{1}, c_{2}\right)$. Then $F_{0}$ admits a restriction to an $H_{3}$ connection $\pi: \hat{F}_{0} \rightarrow \mathcal{Y}$ if and only if $c_{1}=0$.

In this case, the restriction $\hat{F}_{0}$ is uniquely determined, and the connection on $\pi: \hat{F}_{0} \rightarrow \mathcal{Y}$ is regular in the sense of $[\mathrm{Br}]$.

Conversely, given a regular $H_{3}$-connection on $\pi: \hat{F}_{0} \rightarrow \mathcal{Y}$, there is a unique regular torsion free $H_{1,2}$-connection which extends the connection on $\hat{F}_{0}$.

Proof. Let $\pi: F_{0} \rightarrow \mathcal{Z}$ be the torsion free regular $H_{1,2}$-connection. If a restriction on $\hat{F}_{0} \rightarrow \mathcal{Y}$ exists then $T \hat{F}_{0}$ must be annihilated by the ideal

$$
\mathcal{J}=\left\{\theta_{-1,0}-2 \theta_{1,-2}, \theta_{1,0}-2 \theta_{-1,2}, \omega_{0, i}^{02}-\omega_{i, 0}^{20}, i=0,1,2\right\} .
$$

Thus, $\mathcal{J}$ must satisfy the Frobenius condition $d \mathcal{J} \equiv 0 \bmod \mathcal{J}$. A calculation using the structure equations (4-1)-(4-4) yields that this is the case if and only if

$$
\begin{equation*}
2 a_{2,0}=3 a_{0,2} \tag{5-1}
\end{equation*}
$$

Taking the exterior derivative $2 d a_{2,0}-3 d a_{0,2} \bmod \mathcal{J}$, we conclude that $\mathbf{b}$ must be of the form

$$
\begin{equation*}
\mathbf{b}=x \otimes b_{x}^{3}+y \otimes b_{y}^{3} \tag{5-2}
\end{equation*}
$$

for some $\mathcal{V}_{3}$-valued function $b^{3}$ where the subscripts stand for partial derivatives.
Let us define $\hat{F}_{0} \subseteq F_{0}$ by (5-1) and (5-2). Then it is evident that any reduction of $F_{0}$ must be contained in $\hat{F}_{0}$.

From the structure equations (4-5) - (4-7) we calculate that the differentials of the components of (5-1) and (5-2) are linearly independent. Also, substituting (5-1) and (5-2) into $f_{1}^{c}$ from Proposition 4.2. we calculate $f_{1}^{c}=0$.

Therefore, $\hat{F}_{0}=\emptyset$ if $c_{1} \neq 0$. Conversely, if $c_{1}=0$ one can verify that $\hat{F}_{0}$ is non-empty and hence an eight dimensional analytic submanifold of $F_{0}$. Moreover, $\operatorname{dim}\left(T \hat{F}_{0} \cap \operatorname{ker} \pi_{*}\right) \equiv 4$, and so $\mathcal{Y}:=\pi\left(\hat{F}_{0}\right)$ is an analytic submainfold of $\mathcal{Z}$. Now it is easy to verify that ( $\pi: \hat{F}_{0} \rightarrow \mathcal{Y}, \hat{\theta}, \hat{\omega}$ ) with $\hat{\theta}$ and $\hat{\omega}$ as in Definition 3.6. is the desired restriction. Of course, (5-1) and (5-2) determine $\hat{F}_{0}$ uniquely.

Note that this restriction is a torsion free $\mathrm{H}_{3}$-connection. The final statement follows from the classification of regular $H_{3}$-connections in $\{\mathrm{Br}]$. They are uniquely determined by two constant parameters, and it left to the reader to verify that these correspond to the constants $c$ and $c_{2}$.

## Remark.

(1) It seems likely that the last statement in Proposition 5.2. holds true even if the $H_{3}$-connection on $\mathcal{Y}$ is not regular, i.e. in this case there should still be an extension to a unique torsion free $H_{1,2}$-connection. There does not seem to be any substantial obstacle to proving this other than the immense calculations required to determine the non-regular $H_{1,2}$-connections.
(2) Since every torsion free holomorphic $G_{3}$-connection is equivalent to the moduli space of contact curves in a contact threefold $\mathcal{W}[\mathrm{Br}]$, it follows from the results in $\S 3$ that every holomorphic torsion free $G_{3}$-connection can be extended to a $G_{1,2}$-connection whose torsion is given as in the proof of Theorem 3.13.

A characterization of $\mathrm{H}_{3}$-connections is therefore that they are precisely those $G_{3}$-connections which can be extended to a torsion free $G_{1,2}$-connection. (cf. Theorem 0.4.)
(3) A somewhat surprising aspect comes from a comparison of Proposition 5.1. and Proposition 5.2. Namely, if $\mathcal{Y}$ admits a regular torsion free $H_{3}$-connection then on the one hand, by (2), the connection on $\mathcal{Y}$ can be extended to a connection on the moduli space $\mathcal{Z}$ of rational curves in $\mathcal{W}$.

On the other hand, if we let $\mathcal{Z}^{\prime}$ be the torsion free extension from Proposition 5.2. then it follows from Proposition 5.1. that $\mathcal{Z}^{\prime}$ is different from $\mathcal{Z}$ unless both $\mathcal{Z}$ and $\mathcal{Y}$ are flat: indeed, the only locally symmetric $H_{3}-$ connection is the flat one. (cf. Theorem 0.1.)

In other words, the extension $\mathcal{Z}$ of $\mathcal{Y}$ which seems most natural in the geometric sense is different from the extension $\mathcal{Z}^{\prime}$ of $\mathcal{Y}$ which is most natural from the torsion point of view.

Definition 5.3. Let $\mathcal{P}$ be a complex five dimensional manifold. A linear rank 2 Pfaffian system on $\mathcal{P}$ or, for short, a Pfaffian structure on $\mathcal{P}$ is a differential ideal $\mathcal{I}$ on $\mathcal{P}$ with the property that, locally, there is a holomorphic coframe $\kappa_{1}, \kappa_{2}, \alpha, \beta_{1}, \beta_{2}$ on $\mathcal{P}$ such that

$$
\mathcal{I}=\left\{\kappa_{1}, \kappa_{2}\right\}
$$

and

$$
d \kappa_{i}=\alpha \wedge \beta_{i} \quad \bmod \mathcal{I}, \quad i=1,2
$$

A curve $C \subseteq \mathcal{P}$ is called an integral curve if the tangent vectors of $C$ are anihilated by $\mathcal{I}$.

A Pfaffian structure on $\mathcal{P}$ may also be regarded as a rank 2 subbundle $L \subseteq T^{*} \mathcal{P}$ where $L$ is locally spanned by $\kappa_{1}$ and $\kappa_{2}$.

For example, if $\mathcal{W}$ is any three dimensional manifold then $\mathcal{P}:=\mathbb{P} T \mathcal{W}$ carries a canonical Pfaffian structure [EDS]. Namely, for local coordinates $(x, y, z)$ and $(x, y, z, u, v)$ on $\mathcal{W}$ and $\mathcal{P}$ respectively such that the bundle map $\pi: \mathcal{P} \rightarrow \mathcal{W}$ is given by $(x, y, z, u, v) \mapsto(x, y, z)$, this system is given as $\mathcal{I}:=\{d y-u d x, d z-v d x\}$.

Thus, for a curve of the form $(x, y(x), z(x))$ in $\mathcal{W}$ there is a unique integral lift to $\mathcal{P}$, namely $\left(x, y(x), z(x), y^{\prime}(x), z^{\prime}(x)\right)$.

A key observation is now given by the following
Theorem 5.4. Let $\pi: F \rightarrow \mathcal{Z}$ be a holomorphic $G_{1,2}$-connection whose torsion is of the form of Theorem 3.11. Then, locally, $\mathcal{Z}$ is (contained in) the moduli space of all integral curves $C$ of a Pfaffian structure $\mathcal{I}$ on some fivefold $\mathcal{P}$.

Proof. The proof requires to compute the structure equations for connections whose torsion is of the required form. Since these equations are quite complex and since we shall not need them any further, they will be omitted.

It follows from these equations that the differential ideal

$$
\mathcal{J}:=\left\{\theta_{1,0}, \theta_{-1,0}, \theta_{1,-2}, \theta_{-1,-2}, \omega_{0,-2}^{02}\right\}
$$

does satisfy the Frobenius condition $d \mathcal{J} \equiv 0 \bmod \mathcal{J}$. Thus, at least locally, there is a map $p: F \rightarrow \mathcal{P}$ onto some five dimensional complex manifold $\mathcal{P}$ such that $\operatorname{ker}\left(p_{*}\right)=\mathcal{J}^{\perp}$.

For each point $t \in \mathcal{Z}$, we let $C_{t}:=p\left(\pi^{-1}(t)\right)$. It is then easy to see that $C_{t}$ is a rational curve in $\mathcal{P}$, and hence we may regard $\mathcal{Z}$ as the moduli space of certain rational curves in $\mathcal{P}$.

Let $\mathcal{I}_{0}:=\left\{\theta_{1,-2}, \theta_{-1,-2}\right\}$. Then a calculation shows that for each vector field $X \in \mathcal{J}^{\perp}$ on $F, \mathcal{L}_{X}\left(\mathcal{I}_{0}\right) \subseteq \mathcal{I}_{0} \bmod \mathcal{J}$. Therefore, there is a differential system $\mathcal{I}$ on $\mathcal{P}$ such that $p^{*}(\mathcal{I})=\mathcal{I}_{0}$.

Taking the exterior derivatives of $\theta_{1,-2}$ and $\theta_{-1,-2}$ it follows that $\mathcal{I}$ is indeed a Pfaffian structure on $\mathcal{P}$. Moreover, since $\pi^{-1}(t)$ is integral to $\mathcal{I}_{0}$ for all $t \in \mathcal{Z}$ it follows that $C_{t}$ is an integral curve for all $t \in \mathcal{Z}$.

Theorem 5.4. suggests that it should be more natural to regard $G_{3}$-structures, $H_{3}$-structures and $G_{1,2}$-structures as moduli spaces of integral curves of a fivefold with Pfaffian structure rather than as curves in a threefold. Indeed, the remarks preceding Theorem 5.4. indicate how the moduli space of curves in a threefold $\mathcal{W}$ may be regarded merely as a special case of this.

It should also be instructive to see how the local invariants of a Pfaffian structure on $\mathcal{P}[C]$ relate to the associated $G_{1,2}$-structure. This will be pursued in a sequel of the present paper.
